PREFACE

The first edition of the *Handbook of Organic Chemistry* was edited by Professor John A. Dean. It appeared in 1987 and has served as a widely used and convenient reference work for more than 15 years. When Professor Dean asked if I would work with him to develop a second edition, I was pleased to do so. I felt that as valuable as the first edition was, it would be more broadly useful if it contained discussions of the data, the means by which the data were acquired, and perhaps even how the data are applied in modern science. We thus began the revision with enhanced usability as the foremost goal. Sadly, just as we were beginning the effort, Professor Dean passed away. He will be sorely missed.

In following the original plan, many figures, structures, discussions of the methods, and illustrations of the data have been incorporated. Some tables have been reorganized. In some cases tables have been printed twice; although they contain the same data, they are arranged by different criteria. The intent is to make the data easier for the researcher to access and use. Some Internet addresses that can serve as a supplementary resource are included. Despite the numerous additions, the volume remains compact and accessible.

As Professor Dean was not involved in producing this edition, I take responsibility for errors of fact or omission. I hope the volume is error-free, but I would appreciate being informed of any mistakes that are found. Finally, I wish to express my thanks to Mrs. Jolanta Pajewska, who helped in improving the manuscript and the proofreading.

GEORGE W. GOKEL

ABOUT THE AUTHOR

George W. Gokel, Ph.D., is a professor of molecular biology and pharmacology and the director of the Chemical Biology Program at Washington University School of Medicine. He lives in Chesterfield, Missouri.

NOMENCLATURE OF ORGANIC COMPOUNDS

The following synopsis of rules for naming organic compounds and the examples given in explanation are not intended to cover all the possible cases. For a more comprehensive and detailed description, see J. Rigaudy and S. P. Klesney, *Nomenclature of Organic Chemistry*, Sections A, B, C, D, E, F, and H, Pergamon Press, Oxford, 1979. This publication contains the recommendations of the Commission on Nomenclature of Organic Chemistry and was prepared under the auspices of the International Union of Pure and Applied Chemistry (IUPAC).

Hydrocarbons and Heterocycles

Alkanes. The saturated open-chain (acyclic) hydrocarbons (C_nH_{2n+2}) have names ending in -ane. The first four members have the trivial names *methane* (CH_4), *ethane* (CH_3CH_3 or C_2H_6), *propane* (C_3H_8), and *butane* (C_4H_{10}). For the remainder of the alkanes, the first portion of the name is derived from the Greek prefix (see Table 11.4) that cites the number of carbons in the alkane followed by -ane with elision of the terminal -a from the prefix, as shown in Table 1.1.

TABLE 1.1 Names of Straight-Chain Alkanes

n^*	Name	n^*	Name	n^*	Name	n^*	Name
1	Methane	11	Undecane‡	21	Henicosane	60	Hexacontane
2	Ethane	12	Dodecane	22	Docosane	70	Heptacontane
3	Propane	13	Tridecane	23	Tricosane	80	Octacontane
4	Butane	14	Tetradecane			90	Nonacontane
5	Pentane	15	Pentadecane	30	Triacontane	100	Hectane
6	Hexane	16	Hexadecane	31	Hentriacontane	110	Decahectane
7	Heptane	17	Heptadecane	32	Dotriacontane	120	Icosahectane
8	Octane	18	Octadecane			121	Henicosahectane
9	Nonane†	19	Nonadecane	40	Tetracontane		
10	Decane	20	Icosane§	50	Pentacontane		

* n = total number of carbon atoms.

† Formerly called enneane.

‡ Formerly called hendecane.

§ Formerly called eicosane.

For branching compounds, the parent structure is the longest continuous chain present in the compound. Consider the compound to have been derived from this structure by replacement of hydrogen by various alkyl groups. Arabic number prefixes indicate the carbon to which the alkyl group is attached. Start numbering at whichever end of the parent structure that results in the lowest-numbered locants. The arabic prefixes are listed in numerical sequence, separated from each other by commas and from the remainder of the name by a hyphen.

If the same alkyl group occurs more than once as a side chain, this is indicated by the prefixes di-, tri-, tetra-, etc. Side chains are cited in alphabetical order (before insertion of any multiplying prefix). The name of a complex radical (side chain) is considered to begin with the first letter of its complete name. Where names of complex radicals are composed of identical words, priority for citation is given to that radical which contains the lowest-numbered locant at the first cited point of difference in the radical. If two or more side chains are in equivalent positions, the one to be assigned the lowest-numbered locant is that cited first in the name. The complete expression for the side chain may be enclosed in parentheses for clarity or the carbon atoms in side chains may be indicated by primed locants.

FIGURE 1.1 Projections for *n*-decane

If hydrocarbon chains of equal length are competing for selection as the parent, the choice goes in descending order to (1) the chain that has the greatest number of side chains, (2) the chain whose side chains have the lowest-numbered locants, (3) the chain having the greatest number of carbon atoms in the smaller side chains, or (4) the chain having the least-branched side chains.

These trivial names may be used for the unsubstituted hydrocarbons only:

Isobutane $(\text{CH}_3)_2\text{CHCH}_3$

Neopentane $(\text{CH}_3)_4\text{C}$

Isopentane $(\text{CH}_3)_2\text{CHCH}_2\text{CH}_3$

Isohexane $(\text{CH}_3)_2\text{CHCH}_2\text{CH}_2\text{CH}_3$

Univalent radicals derived from saturated unbranched alkanes by removal of hydrogen from a terminal carbon atom are named by adding *-yl* in place of *-ane* to the stem name. Thus the alkane *ethane* becomes the radical *ethyl*. These exceptions are permitted for unsubstituted radicals only:

Isopropyl $(\text{CH}_3)_2\text{CH}-$

Isoamyl $(\text{CH}_3)_2\text{CHCH}_2\text{CH}_2-$

Isobutyl $(\text{CH}_3)_2\text{CHCH}_2-$

Neopentyl $(\text{CH}_3)_3\text{CCH}_2-$

sec-Butyl $\text{CH}_3\text{CH}_2\text{CH}(\text{CH}_3)-$

tert-Pentyl $\text{CH}_3\text{CH}_2\text{C}(\text{CH}_3)_2-$

tert-Butyl $(\text{CH}_3)_3\text{C}-$

Isohexyl $(\text{CH}_3)_2\text{CHCH}_2\text{CH}_2\text{CH}_2-$

Note the usage of the prefixes *iso*-, *neo*-, *sec*-, and *tert*-, and note when italics are employed. Italicized prefixes are never involved in alphabetization, except among themselves; thus *sec*-butyl would precede isobutyl, isohexyl would precede isopropyl, and *sec*-butyl would precede *tert*-butyl.

Examples of alkane nomenclature are

5-Ethyl-2,2-dimethyloctane (note cited order)

3-Ethyl-6-methyloctane (note locants reversed)

4,4-Bis(1,1-dimethylethyl)-2-methyloctane

4,4-Bis-1',1'-dimethylethyl-2-methyloctane

4,4-Bis(*tert*-butyl)-2-methyloctane

Bivalent radicals derived from saturated unbranched alkanes by removal of two hydrogen atoms are named as follows: (1) If both free bonds are on the same carbon atom, the ending -ane of the hydrocarbon is replaced with -ylidene. However, for the first member of the alkanes it is methylene rather than methyldiene. Isopropylidene, *sec*-butylidene, and neopentylidene may be used for the unsubstituted group only. (2) If the two free bonds are on different carbon atoms, the straight-chain group terminating in these two carbon atoms is named by citing the number of methylene groups comprising the chain. Other carbons groups are named as substituents. Ethylene is used rather than dimethylene for the first member of the series, and propylene is retained for $\text{CH}_3 - \text{CH} - \text{CH}_2 -$ (but trimethylene is $-\text{CH}_2 - \text{CH}_2 - \text{CH}_2 -$).

Trivalent groups derived by the removal of three hydrogen atoms from the same carbon are named by replacing the ending -ane of the parent hydrocarbon with -ylidyne.

Alkenes and Alkynes. Each name of the corresponding saturated hydrocarbon is converted to the corresponding alkene by changing the ending -ane to -ene. For alkynes the ending is -yne. With more than one double (or triple) bond, the endings are -adiene, -atriene, etc. (or -adiyne, -atriyne, etc.). The position of the double (or triple) bond in the parent chain is indicated by a locant obtained by numbering from the end of the chain nearest the double (or triple) bond; thus $\text{CH}_3\text{CH}_2\text{CH}=\text{CH}_2$ is 1-butene and $\text{CH}_3\text{C}\equiv\text{CCH}_3$ is 2-butyne.

For multiple unsaturated bonds, the chain is so numbered as to give the lowest possible locants to the unsaturated bonds. When there is a choice in numbering, the double

bonds are given the lowest locants, and the alkene is cited before the alkyne where both occur in the name. Examples:

Unsaturated branched acyclic hydrocarbons are named as derivatives of the chain that contains the maximum number of double and/or triple bonds. When a choice exists, priority goes in sequence to (1) the chain with the greatest number of carbon atoms and (2) the chain containing the maximum number of double bonds.

These nonsystematic names are retained:

An example of nomenclature for alkenes and alkynes is

Univalent radicals have the endings -enyl, -ynyl, -dienyl, -diynyl, etc. When necessary, the positions of the double and triple bonds are indicated by locants, with the carbon atom with the free valence numbered as 1. Examples:

These names are retained:

Should there be a choice for the fundamental straight chain of a radical, that chain is selected which contains (1) the maximum number of double and triple bonds, (2) the largest number of carbon atoms, and (3) the largest number of double bonds. These are in descending priority.

Bivalent radicals derived from unbranched alkenes, alkadienes, and alkynes by removing a hydrogen atom from each of the terminal carbon atoms are named by replacing the endings -ene, -diene, and -yne by -enylene, -dienylene, and -ynylene, respectively. Positions of double and triple bonds are indicated by numbers when necessary. The name *vinylene* instead of ethenylene is retained for $-\text{CH}=\text{CH}-$.

Monocyclic Aliphatic Hydrocarbons. Monocyclic aliphatic hydrocarbons (with no side chains) are named by prefixing cyclo- to the name of the corresponding open-chain hydrocarbon having the same number of carbon atoms as the ring. Radicals are formed as with the alkanes, alkenes, and alkynes. Examples:

Cyclohexane

Cyclohexyl- (for the radical)

Cyclohexene

1-Cyclohexenyl- (for the radical with the free valence at carbon 1)

1,3-Cyclohexadiene

Cyclohexadienyl- (the unsaturated carbons are given numbers as low as possible, numbering from the carbon atom with the free valence given the number 1)

For convenience, aliphatic rings are often represented by simple geometric figures: a triangle for cyclopropane, a square for cyclobutane, a pentagon for cyclopentane, a hexagon (as illustrated) for cyclohexane, etc. It is understood that two hydrogen atoms are located at each corner of the figure unless some other group is indicated for one or both.

Monocyclic Aromatic Compounds. Except for six retained names, all monocyclic substituted aromatic hydrocarbons are named systematically as derivatives of benzene. Moreover, if the substituent introduced into a compound with a retained trivial name is identical with one already present in that compound, the compound is named as a derivative of benzene. These names are retained:

Cumene

Cymene (all three forms; *para*- shown)

Mesitylene

Styrene

Toluene

Xylene (all three forms; *meta*- shown)

The position of substituents is indicated by numbers, with the lowest locant possible given to substituents. When a name is based on a recognized trivial name, priority for lowest-numbered locants is given to substituents implied by the trivial name. When only two substituents are present on a benzene ring, their position may be indicated by *o*- (*ortho*-), *m*- (*meta*-), and *p*- (*para*-) (and alphabetized in the order given) used in place of 1,2-, 1,3-, and 1,4-, respectively.

Radicals derived from monocyclic substituted aromatic hydrocarbons and having the free valence at a ring atom (numbered 1) are named phenyl (for benzene as parent, since benzyl is used for the radical $\text{C}_6\text{H}_5\text{CH}_2-$), cumenyl, mesityl, tolyl, and xylyl. All other radicals are named as substituted phenyl radicals. For radicals having a single free valence in the side chain, these trivial names are retained:

Benzyl $\text{C}_6\text{H}_5\text{CH}_2-$	Phenethyl $\text{C}_6\text{H}_5\text{CH}_2\text{CH}_2-$
Benzhydryl (alternative to diphenylmethyl) $(\text{C}_6\text{H}_5)_2\text{CH}-$	Styryl $\text{C}_6\text{H}_5\text{CH}=\text{CH}-$
Cinnamyl $\text{C}_6\text{H}_5\text{CH}=\text{CH}-\text{CH}_2-$	Trityl $(\text{C}_6\text{H}_5)_3\text{C}-$

Otherwise, radicals having the free valence(s) in the side chain are named in accordance with the rules for alkanes, alkenes, or alkynes.

The name *phenylene* (*o*-, *m*-, or *p*-) is retained for the radical $-\text{C}_6\text{H}_4-$. Bivalent radicals formed from substituted benzene derivatives and having the free valences at ring atoms are named as substituted phenylene radicals, with the carbon atoms having the free valences being numbered 1,2-, 1,3-, or 1,4-, as appropriate.

Radicals having three or more free valences are named by adding the suffixes -triyl, -tetrayl, etc. to the systematic name of the corresponding hydrocarbon.

Fused Polycyclic Hydrocarbons. The names of polycyclic hydrocarbons containing the maximum number of conjugated double bonds end in -ene. Here the ending does not denote one double bond. Names of hydrocarbons containing five or more fixed benzene rings in a linear arrangement are formed from a numerical prefix (see Table 11.4) followed by -acene. A partial list of the names of polycyclic hydrocarbons is given in Table 1.2. Many names are trivial.

Numbering of each ring system is fixed, as shown in Table 1.2, but it follows a systematic pattern. The individual rings of each system are oriented so that the greatest number of rings are (1) in a horizontal row and (2) the maximum number of rings are above and to the right (upper-right quadrant) of the horizontal row. When two orientations meet these requirements, the one is chosen that has the fewest rings in the lower-left quadrant. Numbering proceeds in a clockwise direction, commencing with the carbon atom not engaged in ring fusion that lies in the most counterclockwise position of the uppermost ring (upper-right quadrant); omit atoms common to two or more rings. Atoms common to two or more rings are designated by adding lowercase roman letters to the number of the position immediately preceding. Interior atoms follow the highest number, taking a clockwise sequence wherever there is a choice. Anthracene and phenanthrene are two exceptions to the rule on numbering. Two examples of numbering follow:

When a ring system with the maximum number of conjugated double bonds can exist in two or more forms differing only in the position of an "extra" hydrogen atom, the name can be made specific by indicating the position of the extra hydrogen(s). The compound name is modified with a locant followed by an italic capital *H* for each of these hydrogen atoms. Carbon atoms that carry an indicated hydrogen atom are numbered as low as possible. For example, 1*H*-indene is illustrated in Table 1.2; 2*H*-indene would be

Names of polycyclic hydrocarbons with less than the maximum number of noncumulative double bonds are formed from a prefix dihydro-, tetrahydro-, etc., followed by the

name of the corresponding unreduced hydrocarbon. The prefix perhydro- signifies full hydrogenation. For example, 1,2-dihydronaphthalene is

TABLE 1.2 Fused Polycyclic Hydrocarbons

Listed in order of increasing priority for selection as parent compound

Asterisk after a compound denotes exception to systematic numbering.

1. Pentalene

2. Indene

3. Naphthalene

4. Azulene

5. Heptalene

6. Biphenylene

7. *asym*-Indacene

8. *sym*-Indacene

9. Acenaphthylene

10. Fluorene

11. Phenalene

12. Phenanthrene*

13. Anthracene*

14. Fluoranthene

15. Acephenanthrylene

16. Aceanthrylene

<p>18. Pyrene</p> 	<p>20. Naphthacene</p> 

Examples of retained names and their structures are as follows:

Indan

Acenaphthene

Aceanthrene

Polycyclic compounds in which two rings have two atoms in common or in which one ring contains two atoms in common with each of two or more rings of a contiguous series of rings and which contain at least two rings of five or more members with the maximum number of noncumulative double bonds and which have no accepted trivial name (Table 1.2) are named by prefixing to the name of the parent ring or ring system designations of the other components. The parent name should contain as many rings as possible (provided it has a trivial name) and should occur as far as possible from the beginning of the list in Table 1.2. Furthermore, the attached component(s) should be as simple as possible. For example, one writes dibenzo phenanthrene and not naphthophenanthrene because the attached component benzo- is simpler than naphtho-. Prefixes designating attached components are formed by changing the ending -ene into -eno-; for example, indeno- from

indene. Multiple prefixes are arranged in alphabetical order. Several abbreviated prefixes are recognized; the parent is given in parentheses:

Acenaphtho-	(acenaphthylene)	Naphtho-	(naphthalene)
Anthra-	(anthracene)	Perylo-	(perylene)
Benzo-	(benzene)	Phenanthro-	(phenanthrene)

For monocyclic prefixes other than benzo-, the following names are recognized, each to represent the form with the maximum number of noncumulative double bonds: cyclopenta-, cyclohepta-, cycloocta-, etc.

Isomers are distinguished by lettering the peripheral sides of the parent beginning with *a* for the side 1,2-, and so on, lettering every side around the periphery. If necessary for clarity, the numbers of the attached position (1,2-, for example) of the substituent ring are also denoted. The prefixes are cited in alphabetical order. The numbers and letters are enclosed in square brackets and placed immediately after the designation of the attached component. Examples are

Benz[α]anthraceneAnthra[2,1- α]naphthacene

Bridged Hydrocarbons. Saturated alicyclic hydrocarbon systems consisting of two rings that have two or more atoms in common take the name of the open-chain hydrocarbon containing the same total number of carbon atoms and are preceded by the prefix bicyclo-. The system is numbered commencing with one of the bridgeheads, numbering proceeding by the longest possible path to the second bridgehead. Numbering is then continued from this atom by the longer remaining unnumbered path back to the first bridgehead and is completed by the shortest path from the atom next to the first bridgehead. When a choice in numbering exists, unsaturation is given the lowest numbers. The number of carbon atoms in each of the bridges connecting the bridgeheads is indicated in brackets in descending order. Examples are

Bicyclo[3.2.1]octane

Bicyclo[5.2.0]nonane

Hydrocarbon Ring Assemblies. Assemblies are two or more cyclic systems, either single rings or fused systems, that are joined directly to each other by double or single bonds. For identical systems naming may proceed (1) by placing the prefix bi- before the name of the corresponding radical or (2) for systems joined through a single bond, by placing the prefix bi- before the name of the corresponding hydrocarbon. In each case, the numbering of the assembly is that of the corresponding radical or hydrocarbon, one system being assigned unprimed numbers and the other primed numbers. The points of attachment

are indicated by placing the appropriate locants before the name; an unprimed number is considered lower than the same number primed. The name *biphenyl* is used for the assembly consisting of two benzene rings. Examples are

1,1'-Bicyclopropyl or 1,1'-bicyclopropane

2-Ethyl-2'-propylbiphenyl

For nonidentical ring systems, one ring system is selected as the parent and the other systems are considered as substituents and are arranged in alphabetical order. The parent ring system is assigned unprimed numbers. The parent is chosen by considering the following characteristics in turn until a decision is reached: (1) the system containing the larger number of rings, (2) the system containing the larger ring, (3) the system in the lowest state of hydrogenation, and (4) the highest-order number of ring systems set forth in Table 1.2. Examples are given, with the deciding priority given in parentheses preceding the name:

- (1) 2-Phenylnaphthalene
- (2) and (4) 2-(2'-Naphthyl)azulene
- (3) Cyclohexylbenzene

Radicals from Ring Systems. Univalent substituent groups derived from polycyclic hydrocarbons are named by changing the final *e* of the hydrocarbon name to -yl. The carbon atoms having free valences are given locants as low as possible consistent with the fixed numbering of the hydrocarbon. Exceptions are naphthyl (instead of naphthalenyl), anthryl (for anthracenyl), and phenanthryl (for phenanthrenyl). However, these abbreviated forms are used only for the simple ring systems. Substituting groups derived from fused derivatives of these ring systems are named systematically. Substituting groups having two or more free bonds are named as described in Monocyclic Aliphatic Hydrocarbons on p. 1.5.

Cyclic Hydrocarbons with Side Chains. Hydrocarbons composed of cyclic and aliphatic chains are named in a manner that is the simplest permissible or the most appropriate for the chemical intent. Hydrocarbons containing several chains attached to one cyclic nucleus are generally named as derivatives of the cyclic compound, and compounds containing several side chains and/or cyclic radicals attached to one chain are named as derivatives of the acyclic compound. Examples are

- | | |
|-----------------------------|--------------------------------|
| 2-Ethyl-1-methylnaphthalene | Diphenylmethane |
| 1,5-Diphenylpentane | 2,3-Dimethyl-1-phenyl-1-hexene |

Recognized trivial names for composite radicals are used if they lead to simplifications in naming. Examples are

- | | |
|----------------------|---|
| 1-Benzyl-naphthalene | 1,2,4-Tris(3- <i>p</i> -tolylpropyl)benzene |
|----------------------|---|

Fulvene, for methylenecyclopentadiene, and stilbene, for 1,2-diphenylethylene, are trival names that are retained.

Heterocyclic Systems. Heterocyclic compounds can be named by relating them to the corresponding carbocyclic ring systems by using replacement nomenclature. Heteroatoms are denoted by prefixes ending in *-a*, as shown in Table 1.3. If two or more replacement prefixes are required in a single name, they are cited in the order of their listing in the table. The lowest possible numbers consistent with the numbering of the corresponding carbocyclic system are assigned to the heteroatoms and then to carbon atoms bearing double

TABLE 1.3 Specialist Nomenclature for Heterocyclic Systems

Heterocyclic atoms are listed in decreasing order of priority

Element	Valence	Prefix	Element	Valence	Prefix
Oxygen	2	Oxa-	Antimony	3	Stiba-*
Sulfur	2	Thia-	Bismuth	3	Bisma-
Selenium	2	Selena-	Silicon	4	Sila-
Tellurium	2	Tellura-	Germanium	4	Germa-
Nitrogen	3	Aza-	Tin	4	Stanna-
Phosphorus	3	Phospha-*	Lead	4	Plumba-
Arsenic	3	Arsa-*	Boron	3	Bora-
			Mercury	2	Mercura-

* When immediately followed by *-in* or *-ine*, *phospha-* should be replaced by *phosphor-*, *arsa-* by *arsen-*, and *stiba-* by *antimon-*. The saturated six-membered rings corresponding to phosphorin and arsenin are named *phosphorinane* and *arsenane*. A further exception is the replacement of borin by borinane.

TABLE 1.4 Suffixes for Specialist Nomenclature of Heterocyclic Systems

Number of ring members	Rings containing nitrogen		Rings containing no nitrogen	
	Unsaturation*	Saturation	Unsaturation*	Saturation
3	-irine	-iridine	-irene	-irane
4	-ete	-etidine	-ete	-etane
5	-ole	-olidine	-ole	-olane
6	-ine†	‡	-in	-ane§
7	-epine	‡	-epin	-epane
8	-ocine	‡	-ocin	-ocane
9	-onine	‡	-onin	-onane
10	-ecine	‡	-ecin	-ecane

* Unsaturation corresponding to the maximum number of noncumulative double bonds. Heteroatoms have the normal valences given in Table 1.3.

† For phosphorus, arsenic, antimony, and boron, see the special provisions in Table 1.3.

‡ Expressed by prefixing *perhydro-* to the name of the corresponding unsaturated compound.

§ Not applicable to silicon, germanium, tin, and lead; *perhydro-* is prefixed to the name of the corresponding unsaturated compound.

or triple bonds. Locants are cited immediately preceding the prefixes or suffixes to which they refer. Multiplicity of the same heteroatom is indicated by the appropriate prefix in the series: di-, tri-, tetra-, penta-, hexa-, etc.

If the corresponding carbocyclic system is partially or completely hydrogenated, the additional hydrogen is cited using the appropriate *H*- or hydro- prefixes. A trivial name from Tables 1.5 and 1.6, if available, along with the state of hydrogenation may be used. In the specialist nomenclature for heterocyclic systems, the prefix or prefixes from

TABLE 1.6 Trivial Names for Heterocyclic Systems that are Not Recommended for Use in Fusion Names*Listed in order of increasing priority*

Structure	Parent name	Radical name	Structure	Parent name	Radical name
	Isochroman	Isochromanyl		Pyrazoline (3-shown*)	Pyrazolynyl
	Chroman	Chromanyl		Piperidine	Piperidyl†
	Pyrrolidine	Pyrrolidinyl		Piperazine	Piperazinyl
	Pyrroline (2-shown*)	Pyrrolinyl		Indoline	Indolinyl
	Imidazolidine	Imidazolidinyl		Isoindoline	Isoindolinyl
	Imidazoline (2-shown*)	Imidazolynyl		Quinuclidine	Quinuclidinyl
	Pyrazolidine	Pyrazolidinyl		Morpholine	Morpholinyl‡

* Denotes position of double bond.

† For 1-piperidyl, use piperidino.

‡ For 4-morpholinyl, use morpholino.

Table 1.3 are combined with the appropriate stem from Table 1.4, eliding an *-a* where necessary. Examples of acceptable usage, including (1) replacement and (2) specialist nomenclature, are

- (1) 1-Oxa-4-azacyclohexane
(2) 1,4-Oxazoline Morpholine

- (1) 1,3-Diazacyclohex-5-ene
(2) 1,2,3,4-Tetrahydro-1,3-diazine

- (1) Thiacyclopropane
(2) Thiirane Ethylene sulfide

Radicals derived from heterocyclic compounds by removal of hydrogen from a ring are named by adding *-yl* to the names of the parent compounds (with elision of the final *e*, if present). These exceptions are retained:

Furyl (from furan)	Furfuryl (for 2-furylmethyl)
Pyridyl (from pyridine)	Furfurylidene (for 2-furylmethylene)
Piperidyl (from piperidine)	Thienyl (from thiophene)
Quinolyl (from quinoline)	Thenylidyne (for thienylmethylidyne)
Isoquinolyl	Furfurylidyne (for 2-furylmethylidyne)
Thenylidene (for thienylmethylene)	Thenyl (for thienylmethyl)

Also, piperidino- and morpholino- are preferred to 1-piperidyl- and 4-morpholinyl-, respectively.

If there is a choice among heterocyclic systems, the parent compound is decided in the following order of preference:

1. A nitrogen-containing component
2. A component containing a heteroatom, in the absence of nitrogen, as high as possible in Table 1.3
3. A component containing the greatest number of rings
4. A component containing the largest possible individual ring
5. A component containing the greatest number of heteroatoms of any kind
6. A component containing the greatest variety of heteroatoms
7. A component containing the greatest number of heteroatoms first listed in Table 1.3

If there is a choice between components of the same size containing the same number and kind of heteroatoms, choose as the base component that one with the lower numbers for the heteroatoms before fusion. When a fusion position is occupied by a heteroatom, the names of the component rings to be fused are selected to contain the heteroatom.

Common Names of Heterocycles Used Broadly in Biology. The naming of heterocycles by systematic methods is important but cumbersome for designating some of the most commonly occurring heterocycles. In particular, the bases that occur in ribonucleic acids (RNA) and deoxyribonucleic acids (DNA) have specific substitution patterns. Because they occur so commonly, they have been given trivial names that are invariably used when discussed or named in the biological literature.

Base pairing is the most common (Watson-Crick) arrangement.

The individual elements of RNA and DNA chains.

FIGURE 1.2 Base pairing in the most common (Watson-Crick) arrangement. The individual elements of RNA and DNA chains are shown in the lower panel of the figure. Hollow arrows indicate the points at which the 5'-hydroxyl group is esterified to the 3'-phosphate group to form the so-called "sugar-phosphate" backbone. Note the hydroxyl group (arrow) that is present on ribose but missing in deoxyribose.

The structural frameworks of DNA and RNA are organized by hydrogen bond formation between pairs of purine and pyrimidine bases. The pyrimidines are shown near the end of Table 1.5. Cytosine (C) and thymine (T) occur in DNA and form hydrogen-bonded pairs with the purines guanine (G) and adenine (A), respectively. The base pairs are abbreviated AT and GC, sometimes with dotted lines connecting them. The AT pair is held together by two hydrogen bonds and may be represented in shorthand as A::T. Three H-bonds hold together guanine and cytosine, giving G::C. The so-called Watson-Crick base pairing is shown in Figure 1.2. In RNA, uracil replaces thymine but pairing still occurs with adenine to give A::U.

An alternative form of hydrogen bonding between base pairs is designated "Hoogsteen." This type of bonding cannot readily occur in nature because the purine and pyrimidine bases are constrained to long chains that must interact at numerous points.

Functionalized Compounds

There are several types of nomenclature systems that are recognized. Which type to use is sometimes obvious from the nature of the compound. Substitutive nomenclature, in general, is preferred because of its broad applicability, but radicofunctional, additive, and replacement nomenclature systems are convenient in certain situations.

Substitutive Nomenclature. The first step is to determine the kind of characteristic (functional) group for use as the principal group of the parent compound. A characteristic group is a recognized combination of atoms that confers characteristic chemical properties on the molecule in which it occurs. Carbon-to-carbon unsaturation and heteroatoms in rings are considered nonfunctional for nomenclature purposes.

Substitution means the replacement of one or more hydrogen atoms in a given compound by some other kind of atom or group of atoms, functional or nonfunctional. In substitutive nomenclature, each substituent is cited as either a prefix or a suffix to the name of the parent (or substituting radical) to which it is attached; the latter is denoted the parent compound (or parent group if a radical).

In Table 1.7 are listed the general classes of compounds in descending order of preference for citation as suffixes, that is, as the parent or characteristic compound. When oxygen is

TABLE 1.7 Characteristic Groups for Substitutive Nomenclature

Listed in order of decreasing priority for citation as principal group or parent name

Class	Formula*	Prefix	Suffix

* Carbon atoms enclosed in parentheses are included in the name of the parent compound and not in the suffix or prefix.

replaced by sulfur, selenium, or tellurium, the priority for these elements is in the descending order listed. The higher valence states of each element are listed before considering the successive lower valence states. Derivative groups have priority for citation as principal group after the respective parents of their general class.

In Table 1.8 are listed characteristic groups that are cited only as prefixes (never as suffixes) in substitutive nomenclature. The order of listing has no significance for nomenclature purposes.

Systematic names formed by applying the principles of substitutive nomenclature are single words except for compounds named as acids. First one selects the parent compound, and thus the suffix, from the characteristic group listed earliest in Table 1.7. All remaining functional groups are handled as prefixes that precede, in alphabetical order, the parent name. Two examples may be helpful:

Structure 1

Structure 2

TABLE 1.8 Characteristic Groups Cited Only as Prefixes in Substitutive Nomenclature

Characteristic group	Prefix	Characteristic group	Prefix
—Br	Bromo-	—IX ₂	X may be halogen or a radical; dihalogenoiodo- or diacetoxyiodo-, e.g., —ICl ₂ is dichloroiodo-
—Cl	Chloro-	$=N^{\oplus}=N^{\ominus}$	Diazo-
—ClO	Chlorosyl-	—N ₃ , —N=N ⁺ =N [−]	Azido-
—ClO ₂	Chloryl-	—N=O	Nitroso-
—ClO ₃	Perchloryl-	—NO ₂ , —N ⁺ ≡O	Nitro-
—F	Fluoro-	$=N^{\oplus}\begin{matrix} OH \\ O^{\ominus} \end{matrix}$	<i>aci</i> -Nitro-
—I	Iodo-	—OR	R-oxy-; alkoxy- or aryloxy-
—IO	Iodosyl-	—SR	R-thio-; alkylthio- or arylthio-
—IO ₂	Iodyl*	—SeR (—TeR)	R-seleno- (R-telluro-)
—I(OH) ₂	Dihydroxyiodo-		

* Formerly iodoxy-.

Structure 1 contains an ester group and an ether group. Since the ester group has higher priority, the name is ethyl 2-methoxy-6-methyl-3-cyclohexene-1-carboxylate. Structure 2 contains a carbonyl group, an hydroxy group, and a bromo group. The latter is never a suffix. Between the other two, the carbonyl group has higher priority, the parent has -one as suffix, and the name is 4-bromo-1-hydroxy-2-butanone.

Selection of the principal alicyclic chain or ring system is governed by the following selection rules:

1. For purely alicyclic compounds, the selection process proceeds successively until a decision is reached: (a) the maximum number of substituents corresponding to the characteristic group cited earliest in Table 1.7, (b) the maximum number of double and triple bonds considered together, (c) the maximum length of the chain, and (d) the maximum number of double bonds. Additional criteria, if needed for complicated compounds, are given in the IUPAC nomenclature rules.
2. If the characteristic group occurs only in a chain that carries a cyclic substituent, the compound is named as an aliphatic compound into which the cyclic component is substituted; a radical prefix is used to denote the cyclic component. This chain need not be the longest chain.
3. If the characteristic group occurs in more than one carbon chain and the chains are not directly attached to one another, then the chain chosen as parent should carry the largest number of the characteristic group. If necessary, the selection is continued as in rule 1.
4. If the characteristic group occurs only in one cyclic system, that system is chosen as the parent.
5. If the characteristic group occurs in more than one cyclic system, that system is chosen as parent which (a) carries the largest number of the principal group or, failing to reach a decision, (b) is the senior ring system.
6. If the characteristic group occurs both in a chain and in a cyclic system, the parent is that portion in which the principal group occurs in largest number. If the numbers are the same, that portion is chosen which is considered to be the most important or is the senior ring system.

7. When a substituent is itself substituted, all the subsidiary substituents are named as prefixes and the entire assembly is regarded as a parent radical.
8. The seniority of ring systems is ascertained by applying the following rules successively until a decision is reached: (a) all heterocycles are senior to all carbocycles, (b) for heterocycles, the preference follows the decision process described under "Heterocyclic Systems," page 1–12, (c) the largest number of rings, (d) the largest individual ring at the first point of difference, (e) the largest number of atoms in common among rings, (f) the lowest letters in the expression for ring functions, (g) the lowest numbers at the first point of difference in the expression for ring junctions, (h) the lowest state of hydrogenation, (i) the lowest-numbered locant for indicated hydrogen, (j) the lowest-numbered locant for point of attachment (if a radical), (k) the lowest-numbered locant for an attached group expressed as a suffix, (l) the maximum number of substituents cited as prefixes, (m) the lowest-numbered locant for substituents named as prefixes, hydro prefixes, -ene, and -yne, all considered together in one series in ascending numerical order independent of their nature, and (n) the lowest-numbered locant for the substituent named as prefix which is cited first in the name.

Numbering of Compounds. If the rules for aliphatic chains and ring systems leave a choice, the starting point and direction of numbering of a compound are chosen so as to give lowest-numbered locants to these structural factors, if present, considered successively in the order listed below until a decision is reached. Characteristic groups take precedence over multiple bonds.

1. Indicated hydrogen, whether cited in the name or omitted as being conventional.
2. Characteristic groups named as suffix following the ranking order of Table 1.7.
3. Multiple bonds in acyclic compounds; in bicycloalkanes, tricycloalkanes, and polycycloalkanes, double bonds having priority over triple bonds; and in heterocyclic systems whose names end in -etine, -oline, or -olene.
4. The lowest-numbered locant for substituents named as prefixes, hydro prefixes, -ene, and -yne, all considered together in one series in ascending numerical order.
5. The lowest locant for that substituent named as prefix which is cited first in the name.

For cyclic radicals, indicated hydrogen and thereafter the point of attachment (free valency) have priority for the lowest available number.

Prefixes and Affixes. Prefixes are arranged alphabetically and placed before the parent name; multiplying affixes, if necessary, are inserted and *do not* alter the alphabetical order already attained. The parent name includes any syllables denoting a change of ring member or relating to the structure of a carbon chain. Nondetachable parts of parent names include

1. Forming rings: cyclo-, bicyclo-, spiro-;
2. Fusing two or more rings: benzo-, naphtho-, imidazo-;
3. Substituting one ring or chain member atom for another: oxa-, aza-, thia-;
4. Changing positions of ring or chain members: iso-, *sec*-, *tert*-, neo-;
5. Showing indicated hydrogen;
6. Forming bridges: ethano-, epoxy- and;
7. Hydro-.

Prefixes that represent complete terminal characteristic groups are preferred to those representing only a portion of a given group. For example, for the group —C(=O)CH_3 , the prefix (formylmethyl-) is preferred to (oxoethyl-).

The multiplying affixes di-, tri-, tetra-, penta-, hexa-, hepta-, octa-, nona-, deca-, undeca-, and so on are used to indicate a set of *identical* unsubstituted radicals or parent compounds. The forms bis-, tris-, tetrakis-, pentakis-, and so on are used to indicate a set of identical radicals or parent compounds *each substituted in the same way*. The affixes bi-, ter-, quater-, quinque-, sexi-, septi-, octi-, novi-, deci-, and so on are used to indicate the number of identical rings joined together by a single or double bond.

Although multiplying affixes may be omitted for very common compounds when no ambiguity is caused thereby, such affixes are generally included throughout this handbook in alphabetical listings. An example would be ethyl ether for diethyl ether.

Conjunctive Nomenclature. Conjunctive nomenclature may be applied when a principal group is attached to an acyclic component that is directly attached by a carbon-carbon bond to a cyclic component. The name of the cyclic component is attached directly in front of the name of the acyclic component carrying the principal group. This nomenclature is not used when an unsaturated side chain is named systematically. When necessary, the position of the side chain is indicated by a locant placed before the name of the cyclic component. For substituents on the acyclic chain, carbon atoms of the side chain are indicated by Greek letters proceeding from the principal group to the cyclic component. The terminal carbon atom of acids, aldehydes, and nitriles is omitted when allocating Greek positional letters. Conjunctive nomenclature is not used when the side chain carries more than one of the principal group, except in the case of malonic and succinic acids.

The side chain is considered to extend only from the principal group to the cyclic component. Any other chain members are named as substituents, with appropriate prefixes placed before the name of the cyclic component.

When a cyclic component carries more than one identical side chain, the name of the cyclic component is followed by di-, tri-, etc., and then by the name of the acyclic component, and it is preceded by the locants for the side chains. Examples are

When side chains of two or more different kinds are attached to a cyclic component, only the senior side chain is named by the conjunctive method. The remaining side chains are named as prefixes. Likewise, when there is a choice of cyclic component, the senior is chosen. Benzene derivatives may be named by the conjunctive method only when two or more identical side chains are present. Trivial names for oxo carboxylic acids may be used for the acyclic component. If the cyclic and acyclic components are joined by a double bond, the locants of this bond are placed as superscripts to a Greek capital delta that is

inserted between the two names. The locant for the cyclic component precedes that for the acyclic component, e.g., indene- $\Delta^{1,\alpha}$ -acetic acid.

Radicofunctional Nomenclature. The procedures of radicofunctional nomenclature are identical with those of substitutive nomenclature except that suffixes are never used. Instead, the functional class name (Table 1.9) of the compound is expressed as one word and the remainder of the molecule as another that precedes the class name. When the functional class name refers to a characteristic group that is bivalent, the two radicals attached to it are each named, and when different, they are written as separate words arranged in alphabetical order. When a compound contains more than one kind of group listed in Table 1.9, that kind is cited as the functional group or class name that occurs higher in the table, all others being expressed as prefixes.

Radicofunctional nomenclature finds some use in naming ethers, sulfides, sulfoxides, sulfones, selenium analogs of the preceding three sulfur compounds, and azides.

TABLE 1.9 Functional Class Names Used in Radicofunctional Nomenclature

Groups are listed in order of decreasing priority

Group	Functional class names
X in acid derivatives	Name of X (in priority order: fluoride, chloride, bromide, iodide; cyanide, azide; then the sulfur and selenium analogs)
—CN, —NC	Cyanide, isocyanide
>CO	Ketone; then S and Se analogs
—OH	Alcohol; then S and Se analogs
—O—OH	Hydroperoxide
>O	Ether or oxide
>S, >SO, >SO ₂	Sulfide, sulfoxide, sulfone
>Se, >SeO, >SeO ₂	Selenide, selenoxide, selenone
—F, —Cl, —Br, —I	Fluoride, chloride, bromide, iodide
—N ₃	Azide

Replacement Nomenclature. Replacement nomenclature is intended for use only when other nomenclature systems are difficult to apply in the naming of chains containing heteroatoms. When no group is present that can be named as a principal group, the longest chain of carbon and heteroatoms terminating with carbon is chosen and named as though the entire chain were that of an acyclic hydrocarbon. The heteroatoms within this chain are identified by means of prefixes aza-, oxa-, thia-, etc., in the order of priority stated in Table 1.3. Locants indicate the positions of the heteroatoms in the chain. Lowest-numbered locants are assigned to the principal group when such is present. Otherwise, lowest-numbered locants are assigned to the heteroatoms considered together and, if there is a choice, to the heteroatoms cited earliest in Table 1.3. An example is

13-Hydroxy-9,12-dioxa-3,6-diazatridecanoic acid

Specific Functional Groups

Characteristic groups will now be treated briefly in order to expand the terse outline of substitutive nomenclature presented in Table 1.7. Alternative nomenclature will be indicated whenever desirable.

Acetals and Acylals. Acetals, which contain the group $>\text{C}(\text{OR})_2$, where R may be different, are named (1) as dialkoxy compounds or (2) by the name of the corresponding aldehyde or ketone followed by the name of the hydrocarbon radical(s) followed by the word *acetal*. For example, $\text{CH}_3-\text{CH}(\text{OCH}_3)_2$ is named either (1) 1,1-dimethoxyethane or (2) acetaldehyde dimethyl acetal.

A cyclic acetal in which the two acetal oxygen atoms form part of a ring may be named (1) as a heterocyclic compound or (2) by use of the prefix methylenedioxy for the group $-\text{O}-\text{CH}_2-\text{O}-$ as a substituent in the remainder of the molecule. For example,

(1) 1,3-Benzo[*d*]dioxole-5-carboxylic acid

(2) 3,4-Methylenedioxybenzoic acid

Acylals, $\text{R}^1\text{R}^2\text{C}(\text{OCOR}^3)_2$, are named as acid esters:

Butylidene acetate
propionate

α -Hydroxy ketones, formerly called acyloins, had been named by changing the ending -ic acid or -oic acid of the corresponding acid to -oin. They are preferably named by substitutive nomenclature. For example,

Acid Anhydrides. Symmetrical anhydrides of monocarboxylic acids, when unsubstituted, are named by replacing the word *acid* by *anhydride*. Anhydrides of substituted monocarboxylic acids, if symmetrically substituted, are named by prefixing bis- to the name of the acid and replacing the word *acid* by *anhydride*. Mixed anhydrides are named by giving in alphabetical order the first part of the names of the two acids followed by the word *anhydride*, e.g., acetic propionic anhydride or acetic propanoic anhydride. Cyclic anhydrides of polycarboxylic acids, although possessing a heterocyclic structure, are preferably named as acid anhydrides. For example,

1,8;4,5-Naphthalenetetracarboxylic dianhydride. (Note the use of a semicolon to distinguish the pairs of locants.)

Acyl Halides. Acyl halides, in which the hydroxyl portion of a carboxyl group is replaced by a halogen, are named by placing the name of the corresponding halide after that of the acyl radical. When another group is present that has priority for citation as principal group or when the acyl halide is attached to a side chain, the prefix haloformyl- is used as, for example, in fluoroformyl-.

Alcohols and Phenols. The hydroxyl group is indicated by a suffix -ol when it is the principal group attached to the parent compound and by the prefix hydroxy- when another group with higher priority for citation is present or when the hydroxy group is present in a side chain. When confusion may arise in employing the suffix -ol, the hydroxy group is indicated as a prefix; this terminology is also used when the hydroxyl group is attached to a heterocycle, as, for example, in the name 3-hydroxythiophene to avoid confusion with thiophenol (C_6H_5SH). Designations such as isopropanol, *sec*-butanol, and *tert*-butanol are incorrect because no hydrocarbon exists to which the suffix can be added. Many trivial names are retained. These structures are shown in Table 1.10. The radicals ($RO-$) are named by adding -oxy as a suffix to the name of the R radical, e.g., pentyloxy for $CH_3CH_2CH_2CH_2CH_2O-$. These contractions are exceptions: methoxy (CH_3O-), ethoxy (C_2H_5O-), propoxy (C_3H_7O-), butoxy (C_4H_9O-), and phenoxy (C_6H_5O-). For unsubstituted radicals only, one may use isopropoxy [$(CH_3)_2CH-O-$], isobutoxy [$(CH_3)_2CH_2CH-O-$], *sec*-butoxy [$CH_3CH_2CH(CH_3)-O-$], and *tert*-butoxy [$(CH_3)_3C-O-$].

TABLE 1.10 Retained Trivial Names of Alcohols and Phenols with Structures

Allyl alcohol	$CH_2=CHCH_2OH$
<i>tert</i> -Butyl alcohol	$(CH_3)_3COH$
Benzyl alcohol	$C_6H_5CH_2OH$
Phenethyl alcohol	$C_6H_5CH_2CH_2OH$
Ethylene glycol	$HOCH_2CH_2OH$
1,2-Propylene glycol	$CH_3CHOHCH_2OH$
Glycerol	$HOCH_2CHOHCH_2OH$
Pentaerythritol	$C(CH_2OH)_4$
Pinacol	$(CH_3)_2COHCOH(CH_3)_2$
Phenol	C_6H_5OH
Xylitol	$ \begin{array}{c} OH \\ \\ HOCH_2CH-CH-CH-CH_2OH \\ \quad \quad \\ OH \quad \quad OH \end{array} $
Geraniol	$ \begin{array}{c} (CH_3)_2C=CHCH_2CH_2C=CHCH_2OH \\ \quad \quad \quad \\ \quad \quad \quad CH_3 \end{array} $
Phytol	$ \begin{array}{c} CH_3 \\ \\ CH_2CH_2CHCH_2CH_2CH_2CH(CH_3)_2 \\ \quad \quad \quad \\ CH_2CHCH_2CH_2CH_2C=CHCH_2OH \\ \quad \quad \quad \\ CH_3 \quad \quad \quad CH_3 \end{array} $

TABLE 1.10 Retained Trivial Names of Alcohols and Phenols with Structures (*continued*)

Menthyl

Borneol

Cresol (1,4-isomer shown)

Xylenol (2,3-isomer shown)

Carvacrol

Thymol

Naphthol (2-isomer shown)
2-HydroxynaphthaleneAnthrol (9-isomer shown)
9-HydroxyanthracenePhenanthrol (2-isomer shown)
2-HydroxyphenanthrenePyrocatechol
1,2-DihydroxybenzeneResorcinol
1,3-DihydroxybenzeneHydroquinone
1,4-DihydroxybenzenePyrogallol
1,2,3-TrihydroxybenzenePhloroglucinol
1,3,5-TrihydroxybenzenePicric acid
2,4,6-TrinitrophenolStyphnic acid
1,3-Dihydroxy-2,4,6-trinitrobenzene

Bivalent radicals of the form $\text{O}-\text{Y}-\text{O}$ are named by adding -dioxy to the name of the bivalent radicals except when forming part of a ring system. Examples are $\text{O}-\text{CH}_2-\text{O}-$ (methylenedioxy), $\text{O}-\text{CO}-\text{O}-$ (carbonyldioxy), and $\text{O}-\text{SO}_2-\text{O}-$ (sulfonyldioxy). Anions derived from alcohols or phenols are named by changing the final -ol to -olate.

Salts composed of an anion, $\text{RO}-$, and a cation, usually a metal, can be named by citing first the cation and then the RO anion (with its ending changed to -yl oxide), e.g., sodium benzyl oxide for $\text{C}_6\text{H}_5\text{CH}_2\text{ONa}$. However, when the radical has an abbreviated name, such as methoxy, the ending -oxy is changed to -oxide. For example, CH_3ONa is named sodium methoxide (not sodium methylate).

Aldehydes. When the group $-\text{C}(=\text{O})\text{H}$, usually written $-\text{CHO}$, is attached to carbon at one (or both) end(s) of a linear acyclic chain the name is formed by adding the suffix -al (or -dial) to the name of the hydrocarbon containing the same number of carbon atoms. Examples are butanal for $\text{CH}_3\text{CH}_2\text{CH}_2\text{CHO}$ and propanedial for OHCCH_2CHO .

Naming an acyclic polyaldehyde can be handled in two ways. (1) When more than two aldehyde groups are attached to an unbranched chain, the proper affix is added to -carbaldehyde, which becomes the suffix to the name of the longest chain carrying the maximum number of aldehyde groups. The name and numbering of the main chain do not include the carbon atoms of the aldehyde groups. (2) The name is formed by adding the prefix formyl- to the name of the -dial that incorporates the principal chain. Any other chains carrying aldehyde groups are named by the use of formylalkyl- prefixes. Examples are

- (1) 1,2,5-Pentanetricarbaldehyde
(2) 3-Formylheptanedial

- (1) 4-(2-Formylethyl)-3-(formylmethyl)-1,2,7-heptanetricarbaldehyde
(2) 3-Formyl-5-(2-formylethyl)-4-(formylmethyl)nonanedial

When the aldehyde group is directly attached to a carbon atom of a ring system, the suffix -carbaldehyde is added to the name of the ring system, e.g., 2-naphthalenecarbaldehyde. When the aldehyde group is separated from the ring by a chain of carbon atoms, the compound is named (1) as a derivative of the acyclic system or (2) by conjunctive nomenclature, for example, (1) (2-naphthyl)propionaldehyde or (2) 2-naphthalenepropionaldehyde.

An aldehyde group is denoted by the prefix formyl- when it is attached to a nitrogen atom in a ring system or when a group having priority for citation as principal group is present and part of a cyclic system.

When the corresponding monobasic acid has a trivial name, the name of the aldehyde may be formed by changing the ending -ic acid or -oic acid to -aldehyde. Examples are

Formaldehyde	Acrylaldehyde (not acrolein)
Acetaldehyde	Benzaldehyde
Propionaldehyde	Cinnamaldehyde
Butyraldehyde	2-Furaldehyde (not furfural)

The same is true for polybasic acids, with the proviso that all the carboxyl groups must be changed to aldehyde; then it is not necessary to introduce affixes. Examples are

Glyceraldehyde	Succinaldehyde
Glycolaldehyde	Phthalaldehyde (<i>o</i> -, <i>m</i> -, <i>p</i> -)
Malonaldehyde	

These trivial names may be retained: citral (3,7-dimethyl-2,6-octadienal), vanillin (4-hydroxy-3-methoxybenzaldehyde), and piperonal (3,4-methylenedioxybenzaldehyde).

Amides. For primary amides the suffix -amide is added to the systematic name of the parent acid. For example, $\text{CH}_3\text{—CO—NH}_2$ is acetamide. Oxamide is retained for $\text{H}_2\text{N—CO—CO—NH}_2$. The name -carboxylic acid is replaced by -carboxamide.

For amino acids having trivial names ending in -ine, the suffix -amide is added after the name of the acid (with elision of -e for monoamides). For example, $\text{H}_2\text{N—CH}_2\text{—CO—NH}_2$ is glycineamide.

In naming the radical R—CO—NH— , either (1) the -yl ending of RCO— is changed to -amido or (2) the radicals are named as acylamino radicals. For example,

The latter nomenclature is always used for amino acids with trivial names.

N-substituted primary amides are named either (1) by citing the substituents as *N* prefixes or (2) by naming the acyl group as an *N* substituent of the parent compound. For example,

Amines. Amines are preferably named by adding the suffix -amine (and any multiplying affix) to the name of the parent radical. Examples are

$\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{NH}_2$	Pentylamine
$\text{H}_2\text{NCH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{NH}_2$	1,5-Pentyl diamine or pentamethylenediamine

Locants of substituents of symmetrically substituted derivatives of symmetrical amines are distinguished by primes or else the names of the complete substituted radicals are enclosed in parentheses. Unsymmetrically substituted derivatives are named similarly or as *N*-substituted products of a primary amine (after choosing the most senior of the radicals to be the parent amine). For example,

Complex cyclic compounds may be named by adding the suffix -amine or the prefix amino- (or aminoalkyl-) to the name of the parent compound. Thus three names are permissible for

- (1) 4-Pyridylamine
- (2) 4-Pyridinamine
- (3) 4-Aminopyridine

Complex linear polyamines are best designated by replacement nomenclature. These trivial names are retained: aniline, benzidine, phenetidine, toluidine, and xylydine.

The bivalent radical —NH— linked to two identical radicals can be denoted by the prefix imino-, as well as when it forms a bridge between two carbon ring atoms. A trivalent nitrogen atom linked to three identical radicals is denoted by the prefix nitrilo-. Thus ethylenedi- aminetetraacetic acid (an allowed exception) should be named ethylenedinitrilotetraacetic acid.

Ammonium Compounds. Salts and hydroxides containing quadrivalent nitrogen are named as a substituted ammonium salt or hydroxide. The names of the substituting radicals precede the word *ammonium*, and then the name of the anion is added as a separate word. For example, $(\text{CH}_3)_4\text{N}^+\text{I}^-$ is tetramethylammonium iodide.

When the compound can be considered as derived from a base whose name does not end in -amine, its quaternary nature is denoted by adding -ium to the name of that base (with elision of -e), substituent groups are cited as prefixes, and the name of the anion is added separately at the end. Examples are

Anilinium hydrogen sulfate
Dianilinium hexachloroplatinate

The names *choline* and *betaine* are retained for unsubstituted compounds.

In complex cases, the prefixes amino- and imino- may be changed to ammonio- and iminio- and are followed by the name of the molecule representing the most complex group attached to this nitrogen atom and are preceded by the names of the other radicals attached to this nitrogen. Finally the name of the anion is added separately. For example, the name might be 1-trimethylammonioacridine chloride or 1-acridinyltrimethylammonium chloride.

When the preceding rules lead to inconvenient names, then (1) the unaltered name of the base may be used followed by the name of the anion or (2) for salts of hydrohalogen acids only the unaltered name of the base is used followed by the name of the hydrohalide. An example of the latter would be 2-ethyl-*p*-phenylenediamine monohydrochloride.

Azo Compounds. When the azo group (—N=N—) connects radicals derived from identical unsubstituted molecules, the name is formed by adding the prefix azo- to the name of the parent unsubstituted molecules. Substituents are denoted by prefixes and suffixes. The azo group has priority for lowest-numbered locant. Examples are azobenzene for $\text{C}_6\text{H}_5\text{—N=N—C}_6\text{H}_5$, azobenzene-4- sulfonic acid for $\text{C}_6\text{H}_5\text{—N=N—C}_6\text{H}_4\text{SO}_3\text{H}$, and 2',4-dichloroazobenzene-4'-sulfonic acid for $\text{ClC}_6\text{H}_4\text{—N=N—C}_6\text{H}_3\text{ClSO}_3\text{H}$.

When the parent molecules connected by the azo group are different, azo is placed between the complete names of the parent molecules, substituted or unsubstituted. Locants

are placed between the affix azo and the names of the molecules to which each refers. Preference is given to the more complex parent molecule for citation as the first component, e.g., 2-aminonaphthalene-1-azo-(4'-chloro-2'-methylbenzene).

In an alternative method, the senior component is regarded as substituted by $RN=N-$, this group R being named as a radical. Thus 2-(7-phenylazo-2-naphthylazo)anthracene is the name by this alternative method for the compound named anthracene-2-azo-2'-naphthalene-7'-azobenzene.

Azoxy Compounds. Where the position of the azoxy oxygen atom is unknown or immaterial, the compound is named in accordance with azo rules, with the affix azo replaced by azoxy. When the position of the azoxy oxygen atom in an unsymmetrical compound is designated, a prefix *NNO-* or *ONN-* is used. When both the groups attached to the azoxy radical are cited in the name of the compound, the prefix *NNO-* specifies that the second of these two groups is attached directly to $-N(O)-$; the prefix *ONN-* specifies that the first of these two groups is attached directly to $-N(O)-$. When only one parent compound is cited in the name, the prefixed *ONN-* and *NNO-* specify that the group carrying the primed and unprimed substituents is connected, respectively, to the $-N(O)-$ group. The prefix *NON-* signifies that the position of the oxygen atom is unknown; the azoxy group is then written as $-N_2O-$. For example,

2,2',4-Trichloro-*NNO*-azoxybenzene

Boron Compounds. Molecular hydrides of boron are called boranes. They are named by using a multiplying affix to designate the number of boron atoms and adding an Arabic numeral within parentheses as a suffix to denote the number of hydrogen atoms present. Examples are pentaborane(9) for B_5H_9 and pentaborane(11) for B_5H_{11} .

Organic ring systems are named by replacement nomenclature. Three- to ten-membered monocyclic ring systems containing uncharged boron atoms may be named by the specialist nomenclature for heterocyclic systems. Organic derivatives are named as outlined for substitutive nomenclature. The complexity of boron nomenclature precludes additional details; the text by Rigaudy and Klesney should be consulted.

Carboxylic Acids. Carboxylic acids may be named in several ways. (1) $-COOH$ groups replacing CH_3- at the end of the main chain of an acyclic hydrocarbon are denoted by adding -oic acid to the name of the hydrocarbon. (2) When the $-COOH$ group is the principal group, the suffix -carboxylic acid can be added to the name of the parent chain whose name and chain numbering *does not include* the carbon atom of the $-COOH$ group. The former nomenclature is preferred unless use of the ending -carboxylic acid leads to citation of a larger number of carboxyl groups as suffix. (3) Carboxyl groups are designated by the prefix carboxy- when attached to a group named as a substituent or when another group is present that has higher priority for citation as principal group. In all cases, the

principal chain should be linked to as many carboxyl groups as possible even though it might not be the longest chain present. Examples are

(3) 2-(Carboxymethyl)-1,4-hexanedicarboxylic acid

Removal of the OH from the $-\text{COOH}$ group to form the acyl radical results in changing the ending -oic acid to -oyl or the ending -carboxylic acid to -carbonyl. Thus the radical $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CO}-$ is named either pentanoyl or butanecarbonyl. When the hydroxyl has not been removed from all carboxyl groups present in an acid, the remaining carboxyl groups are denoted by the prefix carboxy-. For example, $\text{HOOCCH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CO}-$ is named 6-carboxyhexanoyl.

Many trivial names exist for acids: these are listed in Table 1.11. Generally, radicals are formed by replacing -ic acid by -oyl.* When a trivial name is given to an acyclic monoacid or diacid, the numeral 1 is always given as locant to the carbon atom of a carboxyl group in the acid or to the carbon atom with a free valence in the radical $\text{RCO}-$.

Ethers ($\text{R}^1-\text{O}-\text{R}^2$). In substitutive nomenclature, one of the possible radicals, $\text{R}-\text{O}-$, is stated as the prefix to the parent compound that is senior from among R^1 or R^2 . Examples are methoxyethane for $\text{CH}_3\text{OCH}_2\text{CH}_3$ and butoxyethanol for $\text{C}_4\text{H}_9\text{OCH}_2\text{CH}_2\text{OH}$.

When another principal group has precedence and oxygen is linking two identical parent compounds, the prefix oxy- may be used, as with 2,2'-oxydiethanol for $\text{HOCH}_2\text{CH}_2\text{OCH}_2\text{CH}_2\text{OH}$.

Compounds of the type $\text{RO}-\text{Y}-\text{OR}$, where the two parent compounds are identical and contain a group having priority over ethers for citation as suffix, are named as assemblies of identical units. For example, $\text{HOOC}-\text{CH}_2-\text{O}-\text{CH}_2\text{CH}_2-\text{O}-\text{CH}_2-\text{COOH}$ is named 2,2'-(ethylenedioxy)diacetic acid.

Linear polyethers derived from three or more molecules of aliphatic dihydroxy compounds, particularly when the chain length exceeds ten units, are most conveniently named by open-chain replacement nomenclature. For example, $\text{CH}_3\text{CH}_2-\text{O}-\text{CH}_2\text{CH}_2-\text{O}-\text{CH}_2\text{CH}_3$ could be 3,6-dioxaoctane or (2-ethoxy)ethoxyethane.

An oxygen atom directly attached to two carbon atoms already forming part of a ring system or to two carbon atoms of a chain may be indicated by the prefix epoxy-. For example, $\text{CH}_2-\text{CH}-\text{CH}_2\text{Cl}$ is named 1-chloro-2,3-epoxypropane.

Symmetrical linear polyethers may be named (1) in terms of the central oxygen atom when there is an odd number of ether oxygen atoms or (2) in terms of the central hydrocarbon group when there is an even number of ether oxygen atoms. For example, $\text{C}_2\text{H}_5-\text{O}-\text{C}_4\text{H}_8-\text{O}-\text{C}_4\text{H}_8-\text{O}-\text{C}_2\text{H}_5$ is bis-(4-ethoxybutyl)ether, and 3,6-dioxaoctane (earlier example) could be named 1,2-bis(ethoxy)ethane.

Polyethers and Cyclic Polyethers. During the past several decades, linear and cyclic polyethers have gained considerable prominence. This is largely due to their remarkable ability to complex metallic and organic cations. The linear polyethers of the polyethylene

*Exceptions: formyl, acetyl, propionyl, butyryl, isobutyryl, valeryl, isovaleryl, oxalyl, malonyl, succinyl, glutaryl, furoyl, and thenoyl.

TABLE 1.11 Names of Some Carboxylic Acids

Systematic name	Trivial name	Systematic name	Trivial name
Methanoic	Formic	<i>trans</i> -Methylbutenedioic	Mesaconic*
Ethanoic	Acetic		
Propanoic	Propionic	1,2,2-Trimethyl-1,3-cyclopentanedicarboxylic acid	Camphoric
Butanoic	Butyric		
2-Methylpropanoic	Isobutyric*	Benzenecarboxylic	Benzoic
Pentanoic	Valeric	1,2-Benzenedicarboxylic	Phthalic
3-Methylbutanoic	Isovaleric*	1,3-Benzenedicarboxylic	Isophthalic
2,2-Dimethylpropanoic	Pivalic*	1,4-Benzenedicarboxylic	Terephthalic
Hexanoic	(Caproic)	Naphthalenecarboxylic	Naphthoic
Heptanoic	(Enanthic)	Methylbenzenecarboxylic	Toluic
Octanoic	(Caprylic)	2-Phenylpropanoic	Hydratropic
Decanoic	(Capric)	2-Phenylpropenoic	Atropic
Dodecanoic	Lauric*	<i>trans</i> -3-Phenylpropenoic	Cinnamic
Tetradecanoic	Myristic*	Furancarboxylic	Furoic
Hexadecanoic	Palmitic*	Thiophenecarboxylic	Thenoic
Octadecanoic	Stearic*	3-Pyridinecarboxylic	Nicotinic
		4-Pyridinecarboxylic	Isonicotinic
Ethanedioic	Oxalic		
Propanedioic	Malonic	Hydroxyethanoic	Glycolic
Butanedioic	Succinic	2-Hydroxypropanoic	Lactic
Pentanedioic	Glutaric	2,3-Dihydroxypropanoic	Glyceric

<i>cis</i> -9-Octadecenoic	Oleic	3,4-Methylenedioxybenzoic	Piperonylic
<i>trans</i> -9-Octadecenoic	Elaidic	3,4-Dihydroxybenzoic	Protocatechuic
<i>cis</i> -Butenedioic	Maleic	3,4,5-Trihydroxybenzoic	Gallic
<i>trans</i> -Butenedioic	Fumaric		
<i>cis</i> -Methylbutenedioic	Citraconic*		

The names in parentheses are abandoned but are listed for reference to older literature.

* Systematic names should be used in derivatives formed by substitution on a carbon atom.

glycol type are discussed in Section 10. The cyclic polyethers are called crown ethers if they are monocyclic and cryptands if they are di- or multi-cyclic compounds.

Crown ethers are typically complicated structures and their names have evolved from the convenient, semi-systematic nomenclature developed by the pioneers in the field. The name “crown” was suggested because the cyclic polyethers “crown a cation” when they complex it. The most general naming system consists in identifying the largest cycle and then denoting the number and type of heteroatoms present. The most common repeating unit is ethyleneoxy or $\text{—CH}_2\text{CH}_2\text{O—}$, normally in the form 1,2-ethylenedioxy and this is

presumed to be present unless otherwise noted. Ethylene oxide (oxirane) is the smallest cyclic compound containing this unit. Dioxane is formally its dimer. The trimer, called 9-crown-3, is known but the smallest compound normally considered to be a crown ether is 12-crown-4. 18-Crown-6 has six repeating ethyleneoxy units and is systematically named 1,4,7,10,13,16-hexaoxacyclooctadecane.

Examples of various crown ethers and cryptands are shown here. The top line of compounds may be named readily enough although the problem with this semi-systematic approach is obvious. If two methylenes were added to 18-crown-6, the compound could correctly be called 20-crown-6 but in the absence of unequivocal descriptors, the positions of the 3-carbon bridges would be unclear. The more cumbersome name 1,4,7,11,13,17-hexaoxacycloicosane tells clearly that the longer bridges are adjacent to each other. A similar problem is apparent in the last two entries of the second line. The designations dicyclohexano and dibenzo are clear as to the substituents but not their positions. The semi-systematic nomenclature is widely used, however, because it is so much less cumbersome for most purposes.

An additional nuance in the nomenclature of these compounds concerns their complexes. The open-chained compounds are often referred to as podands and their complexes as podates. The cyclic ethers may also be called coronands and their complexes are therefore coronates. Complexed cryptands are cryptates. The even more complicated structures known as spherands, cavitands, or carcerands are called spherates, cavitates, or carcerates, respectively, when complexed. The combination of a macrocycle (crown ether or coronand) and a sidechain (podand) is typically called a lariat ether.

An alternate nomenclature system based upon IUPAC principles polymer systems has also been developed but it has not been adopted broadly. Using this method, 15-crown-5 would be called cyclo[pentakis(oxyethylene)] instead of 1,4,7,10,13-pentaoxacyclooctadecane. In this case, substituents and other heteroatoms make the names more complex.

Partial ethers of polyhydroxy compounds may be named (1) by substitutive nomenclature or (2) by stating the name of the polyhydroxy compound followed by the name of the etherifying radical(s) followed by the word *ether*. For example,

Cyclic ethers are named either as heterocyclic compounds or by specialist rules of heterocyclic nomenclature. Radicofunctional names are formed by citing the names of the radicals R^1 and R^2 followed by the word *ether*. Thus methoxyethane becomes ethyl methyl ether and ethoxyethane becomes diethyl ether.

Halogen Derivatives. Using substitutive nomenclature, names are formed by adding prefixes listed in Table 1.8 to the name of the parent compound. The prefix perhalo- implies the replacement of all hydrogen atoms by the particular halogen atoms.

Cations of the type $R^1R^2X^+$ are given names derived from the halonium ion, H_2X^+ , by substitution, e.g., diethyliodonium chloride for $(C_2H_5)_2I^+Cl^-$.

These trivial names are retained: bromoform ($CHBr_3$), chloroform ($CHCl_3$), fluoroform (CHF_3), iodoform (CHI_3), phosgene ($COCl_2$), thiophosgene ($CSCl_2$), and dichlorocarbene radical ($\text{>}CCl_2$). Inorganic nomenclature leads to such names as carbonyl and thiocarbonyl halides (COX_2 and CSX_2) and carbon tetrahalides (CX_4).

Hydroxylamines and Oximes. For $RNH-OH$ compounds, prefix the name of the radical R to hydroxylamine. If another substituent has priority as principal group, attach the prefix hydroxyamino- to the parent name. For example, C_6H_5NHOH would be named *N*-phenylhydroxylamine, but $HOCH_2CH_2NHOH$ would be (hydroxyamino)phenol, with the point of attachment indicated by a locant preceding the parentheses.

Compounds of the type R^1NH-OR_2 are named (1) as alkoxyamino derivatives of compound R^1H , (2) as *N,O*-substituted hydroxylamines, (3) as alkoxyamines (even if R^1 is hydrogen), or (4) by the prefix aminooxy- when another substituent has priority for parent name. Examples of each type are as follows:

1. 2-(Methoxyamino)-8-naphthalenecarboxylic acid for $CH_3ONH-C_{10}H_6COOH$
2. *O*-phenylhydroxylamine for $H_2N-O-C_6H_5$ or *N*-phenylhydroxylamine for C_6H_5NH-OH
3. Phenoxyamine for $H_2N-O-C_6H_5$ (not preferred to *O*-phenylhydroxylamine)
4. Ethyl (aminooxy)acetate for $H_2N-O-CH_2CO-OC_2H_5$

Acyl derivatives, $RCO-NH-OH$ and $H_2N-O-CO-R$, are named as *N*-hydroxy derivatives of amides and as *O*-acylhydroxylamines, respectively. The former may also be named as hydroxamic acids. Examples are *N*-hydroxyacetamide for $CH_3CO-NH-OH$ and *O*-acetylhydroxylamine for $H_2N-O-CO-CH_3$. Further substituents are denoted by prefixes with *O*- and/or *N*-locants. For example, $C_6H_5NH-O-C_2H_5$ would be *O*-ethyl-*N*-phenylhydroxylamine or *N*-ethoxylaniline.

For oximes, the word *oxime* is placed after the name of the aldehyde or ketone. If the carbonyl group is not the principal group, use the prefix hydroxyimino-. Compounds with the group $\text{>}N-OR$ are named by a prefix alkyloxyimino- as oxime *O*-ethers or as *O*-substituted oximes. Compounds with the group $\text{>}C=N(O)R$ are named by adding *N*-oxide after the name of the alkylideneamine compound. For amine oxides, add the word *oxide* after the name of the base, with locants. For example, C_5H_5N-O is named pyridine *N*-oxide or pyridine 1-oxide.

Imines. The group $\text{>}C=NH$ is named either by the suffix -imine or by citing the name of the bivalent radical $R^1R^2C\text{<}$ as a prefix to amine. For example, $CH_3CH_2CH_2CH=NH$

could be named 1-butanamine or butylideneamine. When the nitrogen is substituted, as in $\text{CH}_2=\text{N}-\text{CH}_2\text{CH}_3$, the name is *N*-(methylidene) ethylamine.

Quinones are exceptions. When one or more atoms of quinonoid oxygen have been replaced by $>\text{NH}$ or $>\text{NR}$, they are named by using the name of the quinone followed by the word *imine* (and preceded by proper affixes). Substituents on the nitrogen atom are named as prefixes. Examples are

Ketenes. Derivatives of the compound ketene, $\text{CH}_2=\text{C}=\text{O}$, are named by substitutive nomenclature. For example, $\text{C}_4\text{H}_9\text{CH}=\text{C}=\text{O}$ is butyl ketene. An acyl derivative, such as $\text{CH}_3\text{CH}_2-\text{CO}-\text{CH}_2\text{CH}=\text{C}=\text{O}$, may be named as a polyketone, 1-hexene-1,4-dione. Bis-ketene is used for two to avoid ambiguity with diketene (dimeric ketene).

Ketones. Acyclic ketones are named (1) by adding the suffix -one to the name of the hydrocarbon forming the principal chain or (2) by citing the names of the radicals R^1 and R^2 followed by the word *ketone*. In addition to the preceding nomenclature, acyclic monoacyl derivatives of cyclic compounds may be named (3) by prefixing the name of the acyl group to the name of the cyclic compound. For example,

When the cyclic component is benzene or naphthalene, the -ic acid or -oic acid of the acid corresponding to the acyl group is changed to -ophenone or -onaphthone, respectively. For example, $\text{C}_6\text{H}_5-\text{CO}-\text{CH}_2\text{CH}_2\text{CH}_3$ can be named either butyrophenone (or butanophenone) or phenyl propyl ketone.

Radicalofunctional nomenclature can be used when a carbonyl group is attached directly to carbon atoms in two ring systems and no other substituent is present having priority for citation.

When the methylene group in polycarbocyclic and heterocyclic ketones is replaced by a keto group, the change may be denoted by attaching the suffix -one to the name of the ring system. However, when >CH in an unsaturated or aromatic system is replaced by a keto group, two alternative names become possible. (1) The maximum number of noncumulative double bonds is added after introduction of the carbonyl group(s), and any hydrogen that remains to be added is denoted as indicated hydrogen with the carbonyl group having priority over the indicated hydrogen for lower-numbered locant. (2) The prefix oxo- is used, with the hydrogenation indicated by hydro prefixes; hydrogenation is considered

to have occurred before the introduction of the carbonyl group. For example,

- (1) 1(2*H*)-Naphthalenone
(2) 1-Oxo-1,2-dihydronaphthalene

When another group having higher priority for citation as principal group is also present, the ketonic oxygen may be expressed by the prefix oxo-, or one can use the name of the carbonyl-containing radical, as, for example, acyl radicals and oxo-substituted radicals. Examples are

4-(4'-Oxohexyl)-1-benzoic acid

1,2,4-Triacetylbenzene

Diketones and tetraketones derived from aromatic compounds by conversion of two or four $\equiv\text{CH}$ groups into keto groups, with any necessary rearrangement of double bonds to a quinonoid structure, are named by adding the suffix -quinone and any necessary affixes.

Polyketones in which two or more contiguous carbonyl groups have rings attached at each end may be named (1) by the radicofunctional method or (2) by substitutive nomenclature. For example,

- (1) 2-Naphthyl 2-pyridyl diketone
(2) 1-(2-Naphthyl)-2-(2-pyridyl)ethanedione

Some trivial names are retained: acetone (2-propanone), biacetyl (2,3-butanedione), propiophenone ($\text{C}_6\text{H}_5-\text{CO}-\text{CH}_2\text{CH}_3$), chalcone ($\text{C}_6\text{H}_5-\text{CH}=\text{CH}-\text{CO}-\text{C}_6\text{H}_5$), and deoxybenzoin ($\text{C}_6\text{H}_5-\text{CH}_2-\text{CO}-\text{C}_6\text{H}_5$).

These contracted names of heterocyclic nitrogen compounds are retained as alternatives for systematic names, sometimes with indicated hydrogen. In addition, names of oxo derivatives of fully saturated nitrogen heterocycles that systematically end in -idinone are often contracted to end in -idone when no ambiguity might result. For example,

2-Pyridone
2(1*H*)-Pyridone

4-Pyridone
4(1*H*)-Pyridone

2-Quinolone
2(1*H*)-Quinolone

4-Quinolone
4(1*H*)-Quinolone

1-Isoquinolone
1(2*H*)-Isoquinolone

4-Oxazolone
4(5*H*)-Oxazolone

4-Pyrazolone
4(5*H*)-Pyrazolone

5-Pyrazolone
5(4*H*)-Pyrazolone

4-Isloxazoline
4(5*H*)-Isloxazoline

4-Thiazolone
4(5*H*)-Thiazolone

9-Acridone
9(10*H*)-Acridone

Lactones, Lactides, Lactams, and Lactims. When the hydroxy acid from which water may be considered to have been eliminated has a trivial name, the lactone is designated by substituting -olactone for -ic acid. Locants for a carbonyl group are numbered as low as possible, even before that of a hydroxyl group.

Lactones formed from aliphatic acids are named by adding -olide to the name of the nonhydroxylated hydrocarbon with the same number of carbon atoms. The suffix -olide signifies the change of $\text{>CH}\cdots\text{CH}_3$ into $\text{>C}\cdots\text{C}=\text{O}$

Structures in which one or more (but not all) rings of an aggregate are lactone rings are named by placing -carbolactone (denoting the —O—CO— bridge) after the names of the structures that remain when each bridge is replaced by two hydrogen atoms. The locant for —CO— is cited before that for the ester oxygen atom. An additional carbon atom is incorporated into this structure as compared to the -olide.

These trivial names are permitted: γ -butyrolactone, γ -valerolactone, and δ -valerolactone. Names based on heterocycles may be used for all lactones. Thus, γ -butyrolactone is also tetrahydro-2-furanone or dihydro-2(3*H*)-furanone.

Lactides, intermolecular cyclic esters, are named as heterocycles. **Lactams** and **lactims**, containing a —CO—NH— and —C(OH)=N— group, respectively, are named as heterocycles, but they may also be named with -lactam or -lactim in place of -olide. For example,

(1) 2-Pyrrolidinone
(2) 4-Butanellactam

Nitriles and Related Compounds. For acids whose systematic names end in -carboxylic acid, nitriles are named by adding the suffix -carbonitrile when the —CN group replaces the —COOH group. The carbon atom of the —CN group is excluded from the numbering of a chain to which it is attached. However, when the triple-bonded nitrogen atom is considered to replace three hydrogen atoms at the end of the main chain of an acyclic hydrocarbon, the suffix -nitrile is added to the name of the hydrocarbon. Numbering begins with the carbon attached to the nitrogen. For example, $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CN}$ is named (1) pentanecarbonitrile or (2) hexanenitrile.

Trivial acid names are formed by changing the endings -oic acid or -ic acid to -onitrile. For example, CH_3CN is acetonitrile. When the $-\text{CN}$ group is not the highest priority group, the $-\text{CN}$ group is denoted by the prefix cyano-.

In order of decreasing priority for citation of a functional class name, and the prefix for substitutive nomenclature, are the following related compounds:

Functional group	Prefix	Radicofunctional ending
$-\text{NC}$	Isocyano-	Isocyanide
$-\text{OCN}$	Cyanato-	Cyanate
$-\text{NCO}$	Isocyanato-	Isocyanate
$-\text{ONC}$	—	Fulminate
$-\text{SCN}$	Thiocyanato-	Thiocyanate
$-\text{NCS}$	Isothiocyanato-	Isothiocyanate
$-\text{SeCN}$	Selenocyanato-	Selenocyanate
$-\text{NCSe}$	Isoselenocyanato-	Isoselenocyanate

Peroxides. Compounds of the type $\text{R}-\text{O}-\text{OH}$ are named (1) by placing the name of the radical R before the word *hydroperoxide* or (2) by use of the prefix hydroperoxy- when another parent name has higher priority. For example, $\text{C}_2\text{H}_5\text{OOH}$ is ethyl hydroperoxide.

Compounds of the type $\text{R}^1\text{O}-\text{OR}^2$ are named (1) by placing the names of the radicals in alphabetical order before the word *peroxide* when the group $-\text{O}-\text{O}-$ links two chains, two rings, or a ring and a chain, (2) by use of the affix dioxy to denote the bivalent group $-\text{O}-\text{O}-$ for naming assemblies of identical units or to form part of a prefix, or (3) by use of the prefix epidioxy- when the peroxide group forms a bridge between two carbon atoms, a ring, or a ring system. Examples are methyl propyl peroxide for $\text{CH}_3-\text{O}-\text{O}-\text{C}_3\text{H}_7$ and 2,2'-dioxidiacetic acid for $\text{HOOC}-\text{CH}_2-\text{O}-\text{O}-\text{CH}_2-\text{COOH}$.

Phosphorus Compounds. Acyclic phosphorus compounds containing only one phosphorus atom, as well as compounds in which only a single phosphorus atom is in each of several functional groups, are named as derivatives of the parent structures listed in Table 1.12. Often these are purely hypothetical parent structures. When hydrogen attached to phosphorus is replaced by a hydrocarbon group, the derivative is named by substitution nomenclature. When hydrogen of an $-\text{OH}$ group is replaced, the derivative is named by radicofunctional nomenclature. For example, $\text{C}_2\text{H}_5\text{PH}_2$ is ethylphosphine; $(\text{C}_2\text{H}_5)_2\text{PH}$, diethylphosphine; $\text{CH}_3\text{P}(\text{OH})_2$, dihydroxy-methyl-phosphine or methylphosphonous acid; $\text{C}_2\text{H}_5-\text{PO}(\text{Cl})(\text{OH})$, ethylchlorophosphonic acid or ethylphosphonochloridic acid or hydrogen chlorodioxoethylphosphate(V); $\text{CH}_3\text{CH}(\text{PH}_2)\text{COOH}$, 2-phosphinopropionic acid; $\text{HP}(\text{CH}_2\text{COOH})_2$, phosphinediylldiacetic acid; $(\text{CH}_3)_2\text{HP}(\text{O})\text{OH}$, methylphosphinic acid or hydrogen hydridomethyldioxophosphate(V); $(\text{CH}_3\text{O})_3\text{PO}$, trimethyl phosphate; and $(\text{CH}_3\text{O})_3\text{P}$, trimethyl phosphite.

Salts and Esters of Acids. Neutral salts of acids are named by citing the cation(s) and then the anion, whose ending is changed from -oic to -oate or from -ic to -ate. When different acidic residues are present in one structure, prefixes are formed by changing the anion ending -ate to -ato- or -ide to -ido-. The prefix carboxylato- denotes the ionic group $-\text{COO}^-$. The phrase: (metal) salt of (the acid) is permissible when the carboxyl groups are not all named as affixes.

Acid salts include the word *hydrogen* (with affixes, if appropriate) inserted between the name of the cation and the name of the anion (or word *salt*).

TABLE 1.12 Parent Structures of Phosphorus-containing Compounds

Formula	Parent name	Substitutive prefix	Radicalfunctional ending
H ₃ P	Phosphine	H ₂ P— Phosphino-	Phosphide
H ₃ P	Phosphorane	H ₄ P— Phosphoranyl-	—
		H ₃ P< Phosphoroanediyl-	—
		H ₂ P≡ Phosphoranetriyl-	—
H ₃ PO	Phosphine oxide	—	—
H ₃ PS	Phosphine sulfide	—	—
H ₃ PNH	Phosphine imide	—	—
P(OH) ₃	Phosphorous acid	—	Phosphite
HP(OH) ₂	Phosphonous acid	—	Phosphonite
H ₂ POH	Phosphinous acid	—	Phosphinite
P(O)(OH) ₃	Phosphoric acid	P(O)≡ Phosphoryl-	Phosphate(V)
HP(O)(OH) ₂	Phosphonic acid	HP(O)< Phosphonoyl-	Phosphonate
		—P(O)OH ₂ Phosphinoyl-	—
H ₂ P(O)OH	Phosphinic acid	H ₂ P(O)— Phosphinoyl-	Phosphinate
		>P(O)OH Phosphinoco-	—
		Phosphinato-	—

Esters are named similarly, with the name of the alkyl or aryl radical replacing the name of the cation. Acid esters of acids and their salts are named as neutral esters, but the components are cited in the order: cation, alkyl or aryl radical, hydrogen, and anion. Locants are added if necessary. For example,

Ester groups in R¹—CO—OR² compounds are named (1) by the prefix alkoxy carbonyl- or aryloxy carbonyl- for —CO—OR² when the radical R¹ contains a substituent with priority for citation as principal group or (2) by the prefix acyloxy- for R¹—CO—O— when the radical R² contains a substituent with priority for citation as principal group. Examples are

The trivial name *acetoxy* is retained for the CH₃—CO—O— group. Compounds of the type R²C(OR²)₃ are named as R² esters of the hypothetical ortho acids. For example, CH₃C(OCH₃)₃ is trimethyl orthoacetate.

Silicon Compounds. SiH_4 is called silane; its acyclic homologs are called disilane, trisilane, and so on, according to the number of silicon atoms present. The chain is numbered from one end to the other so as to give the lowest-numbered locant in radicals to the free valence or to substituents on a chain. The abbreviated form silyl is used for the radical SiH_3- . Numbering and citation of side chains proceed according to the principles set forth for hydrocarbon chains. Cyclic nonaromatic structures are designated by the prefix cyclo-.

When a chain or ring system is composed entirely of alternating silicon and oxygen atoms, the parent name *siloxane* is used with a multiplying affix to denote the number of silicon atoms present. The parent name *silazane* implies alternating silicon and nitrogen atoms; multiplying affixes denote the number of silicon atoms present.

The prefix *sila-* designates replacement of carbon by silicon in replacement nomenclature. Prefix names for radicals are formed analogously to those for the corresponding carbon-containing compounds. Thus silyl is used for SiH_3- , silylene for $-\text{SiH}_2-$, silyldiyne for $-\text{SiH}-$.

Sulfur Compounds

Bivalent Sulfur. The prefix thio-, placed before an affix that denotes the oxygen-containing group or an oxygen atom, implies the replacement of that oxygen by sulfur. Thus the suffix -thiol denotes $-\text{SH}$, -thione denotes $-(\text{C})=\text{S}$ and implies the presence of an $=\text{S}$ at a nonterminal carbon atom, -thioic acid denotes $[(\text{C})=\text{S}]\text{OH} \rightleftharpoons [(\text{C})=\text{O}]\text{SH}$ (that is, the *O*-substituted acid and the *S*-substituted acid, respectively), -dithioic acid denotes $[-\text{C}(\text{S})]\text{SH}$, and -thial denotes $-(\text{C})\text{HS}$ (or -carbothialdehyde denotes $-\text{CHS}$). When -carboxylic acid has been used for acids, the sulfur analog is named -carbothioic acid or -carbodithioic acid.

Prefixes for the groups $\text{HS}-$ and $\text{RS}-$ are mercapto- and alkylthio-, respectively; this latter name may require parentheses for distinction from the use of thio- for replacement of oxygen in a trivially named acid. Examples of this problem are $4-\text{C}_2\text{H}_5-\text{C}_6\text{H}_4-\text{CSOH}$ named *p*-ethyl(thio)benzoic acid and $4-\text{C}_2\text{H}_5-\text{S}-\text{C}_6\text{H}_4-\text{COOH}$ named *p*-(ethylthio)benzoic acid. When $-\text{SH}$ is not the principal group, the prefix mercapto- is placed before the name of the parent compound to denote an unsubstituted $-\text{SH}$ group.

The prefix thioxo- is used for naming $=\text{S}$ in a thioketone. Sulfur analogs of acetals are named as alkylthio- or arylthio-. For example, $\text{CH}_3\text{CH}(\text{SCH}_3)\text{OCH}_3$ is 1-methoxy-1-(methylthio)ethane. Prefix forms for -carbothioic acids are hydroxy(thiocarbonyl)- when referring to the *O*-substituted acid and mercapto(carbonyl)- for the *S*-substituted acid.

Salts are formed as with oxygen-containing compounds. For example, $\text{C}_2\text{H}_5-\text{S}-\text{Na}$ is named either sodium ethanethiolate or sodium ethyl sulfide. If mercapto- has been used as a prefix, the salt is named by use of the prefix sulfido- for $-\text{S}^-$.

Compounds of the type $\text{R}^1-\text{S}-\text{R}^2$ are named alkylthio- (or arylthio-) as a prefix to the name of R^1 or R^2 , whichever is the senior.

Sulfonium Compounds. Sulfonium compounds of the type $\text{R}^1\text{R}^2\text{R}^3\text{S}^+\text{X}^-$ are named by citing in alphabetical order the radical names followed by -sulfonium and the name of the anion. For heterocyclic compounds, -ium is added to the name of the ring system. Replacement of $>\text{CH}$ by sulfonium sulfur is denoted by the prefix thionia-, and the name of the anion is added at the end.

Organosulfur Halides. When sulfur is directly linked only to an organic radical and to a halogen atom, the radical name is attached to the word *sulfur* and the name(s) and number of the halide(s) are stated as a separate word. Alternatively, the name can be formed from $\text{R}-\text{SOH}$, a sulfenic acid whose radical prefix is sulphenyl-. For example, $\text{CH}_3\text{CH}_2-\text{S}-\text{Br}$ would be named either ethylsulfur monobromide or ethanesulphenyl bromide. When another principal group is present, a composite prefix is formed from the number and substitutive name(s) of the halogen atoms in front of the syllable thio. For example, $\text{BrS}-\text{COOH}$ is (bromothio)formic acid.

Sulfoxides. Sulfoxides, R^1-SO-R^2 , are named by placing the names of the radicals in alphabetical order before the word *sulfoxide*. Alternatively, the less senior radical is named followed by sulfinyl- and concluded by the name of the senior group. For example, $CH_3CH_2-SO-CH_2CH_2CH_3$ is named either ethyl propyl sulfoxide or 1-(ethylsulfinyl)propane.

When an $\geq SO$ group is incorporated in a ring, the compound is named an oxide.

Sulfones. Sulfones, $R^1-SO_2-R^2$, are named in an analogous manner to sulfoxides, using the word *sulfone* in place of *sulfoxide*. In prefixes, the less senior radical is followed by -sulfonyl-. When the $\geq SO_2$ group is incorporated in a ring, the compound is named as a dioxide.

Sulfur Acids. Organic oxy acids of sulfur, that is, $-SO_3H$, $-SO_2H$, and $-SOH$, are named sulfonic acid, sulfinic acid, and sulfenic acid, respectively. In subordinate use, the respective prefixes are sulfo-, sulfinio, and sulfeno-. The grouping $-SO_2-O-SO_2-$ or $-SO-O-SO-$ is named sulfonic or sulfinic anhydride, respectively.

Inorganic nomenclature is employed in naming sulfur acids and their derivatives in which sulfur is linked only through oxygen to the organic radical. For example, $(C_2H_5O)_2SO_2$ is diethyl sulfate and $C_2H_5O-SO_2-OH$ is ethyl hydrogen sulfate. Prefixes *O*- and *S*- are used where necessary to denote attachment to oxygen and to sulfur, respectively, in sulfur replacement compounds. For example, CH_3-S-SO_2-ONa is sodium *S*-methyl thiosulfate.

When sulfur is linked only through nitrogen, or through nitrogen and oxygen, to the organic radical, naming is as follows: (1) *N*-substituted amides are designated as *N*-substituted derivatives of the sulfur amides and (2) compounds of the type $R-NH-SO_3H$ may be named as *N*-substituted sulfamic acids or by the prefix sulfoamino- to denote the group HO_3S-NH- . The groups $-N=SO$ and $-N=SO_2$ are named sulfinylamines and sulfonylamine, respectively.

Sultones and Sultams. Compounds containing the group $-SO_2-O-$ as part of the ring are called -sultone. The $-SO_2-$ group has priority over the $-O-$ group for lowest-numbered locant.

Similarly, the $-SO_2-N-$ group as part of a ring is named by adding -sultam to the name of the hydrocarbon with the same number of carbon atoms. The $-SO_2-$ has priority over $-N=$ for lowest-numbered locant.

Steroids. Steroids are important natural products that have a special nomenclature. They typically consist of three fused 6-membered rings and a four fused 5-membered ring. The

rings are designated A, B, C, and D as shown here. The most common, all *trans* ring fusion is illustrated in the right hand structure. Most steroids that occur naturally possess the two methyl groups ("bridgehead" or angular methyl groups) shown as carbons 18 and 19 at positions 10 and 13, respectively.

Cholesterol is the most common steroid of mammalian membranes. It is formed biologically from lanosterol, as shown. Ergosterol is the most common steroid of fungal membranes. It differs from cholesterol by the presence of two additional double bonds that affect its three dimensional structure. Also shown are three so-called steroid hormones, androsterone, estradiol, and testosterone. Note the presence of an aromatic A-ring in estradiol.

Vitamins. The vitamins are natural organic compounds of considerable diversity that occur widely. The name derives from the Latin *vita* (life) and "amin," a shortened form of amine. The name reflects the historical discovery of these substances, not all of which are amines. They are all of relatively low molecular weight, especially compared to peptides but in a range comparable to steroids. These substances are uniformly active and play various roles in biosynthesis and metabolism. The vitamins are too numerous to detail here but the most common examples are illustrated. They are classed using the common system, that is, water or fat soluble, depending on their approximate level of hydrophobicity or hydrophilicity. Their names are typically nonsystematic but the diversity of their structures requires that the trivial names be used.

Biological Nomenclature

The names assigned to compounds by organic chemists and biologists sometimes differ. Moreover, biological structures are made up of repeating components and rapidly become large and complex molecules. Thus, special terminology has been developed to assist in describing these compounds.

Amino Acids. An amino acid is any organic compound that possesses both amine ($-\text{NH}_2$) and carboxyl ($-\text{COOH}$) groups within the same organic framework. When both functional groups are attached to the same carbon atom, they are designated α -amino acids. These are of special significance in biology as they form the diverse monomer set from which peptides and proteins are built.

Aminoacetic acid is the simplest example of an α -amino acid. Among the 20 biologically most important amino acids, its structure is unique in two ways. First, it possesses no “sidechain” attached to the methylene carbon. Second, the lack of any substituent (other than hydrogen) means that aminoacetic acid, more commonly called glycine, is achiral. The other 19 “essential” or “common” amino acids possess sidechains attached in a stereochemically identical fashion.

The other 19 common α -amino acids have side chains attached at the position represented by R. Among these 19, proline is unique because its sidechain is attached at the other end to the amino nitrogen, which is therefore secondary rather than primary.

The twenty common α -amino acids may be named systematically. For example, when R is methyl, the compound may be called 2-methylaminoacetic acid. It may also correctly be called 2-aminopropanoic acid. By far, however, it is most commonly called alanine.

The names and structures of the twenty natural amino acids are given in Table 1.13. The International Union of Pure and Applied Chemistry (IUPAC) uses the three-letter abbreviations shown in the second column of Table 1.13 to describe amino acids. These are widely used in biological circles as well but are inappropriate when long peptide or protein sequences need to be described. For example, when proinsulin is cleaved, it forms the biologically important peptide insulin and another peptide usually called C-peptide. The human peptide consists of a linear chain of 31 amino acids that have the sequence, from amino to carboxyl, $\text{H}_2\text{N}\text{-Glu-Ala-Glu-Asp-Leu-Gln-Val-Glu-Gln-Glu-Leu-Gly-Gly-Pro-Gly-Ala-Gly-Ser-Leu-Gln-Pro-Leu-Ala-Leu-Glu-Gly-Ser-Leu-Gln-OH}$. This is readily comprehensible to most chemists because the abbreviations are typically the first three letters of the amino acid. Thus, alanine is Ala and arginine is Arg. Aspartic acid and asparagine cannot both be named Asp so the latter is distinguished as Asn.

Biologists often must compare peptides or proteins from different species. If the IUPAC nomenclature was used, the descriptor for this peptide would be about four-fold longer than if the International Union of Biology’s (IUB) single-letter codes are used. Where possible, the first letter of the amino acid’s name is used. As with the three-letter abbreviations, this is not always possible. Alanine is A and aspartic acid is arbitrarily assigned the letter D. Asparagine is called N. Glycine is G so glutamic acid is designated E. Although arbitrary, the name is logical for the homologue of aspartic acid. Glutamine is called Q. Arginine cannot use “A,” which is taken by alanine, but the letter “R” is suggestive and serves as a mnemonic.

When the single-letter abbreviations are used, the human C-peptide sequence reduces to EAEDLQVGQVELGGGPGAGSLQPLALEGSLQ, often written in groups of five letters as EAEDLQVGQVELGGG PGAGS LQPLA LEGSL Q so that the sequence can be more conveniently read and compared with other sequences.

Most of three-letter abbreviations are taken from the first three letters of the name of the corresponding amino acid and are pronounced as written (alanine—Ala, cysteine—Cys). The one-letter symbol for the amino acids is usually the first letter of the amino acid’s name and is often used when comparing the amino acids sequences of several similar proteins.

Note that the single-letter abbreviations permit a fast comparison of the sequences so that their differences and similarities can quickly be discerned. The sequences for C-peptides from humans and from rats are compared below (differences are highlighted):

EAEDI	QVGQV	ELGGG	PGAGS	LQPLA	LEGSL	Q (Human)
EVEDP	QVPQL	ELGGG	PEAGD	LQTLA	LEVAR	Q (Rat)

Ten of the amino acids in each sequence differ. Thus, 21 of the 31 amino acids are identical within the sequence. The sequence homology is said to be $(21/31 \times 100) = 68\%$. It would have been much more difficult to make this comparison using the longer three-letter abbreviations. For a protein having 200 or 300 amino acids, the problem becomes correspondingly greater.

Despite the greater economy of using single letter amino acid abbreviations, it is the three-letter abbreviations that have become shortened names for the essential amino acids. For example, practicing scientists would identify the sequence GPAGW as “Gly-Pro-Ala-Gly-Try.” A sequence containing both aspartic acid and asparagine such as GAGE would be referred to in conversation as “Gly-Asp-Gly-Asparagine.”

Formally, however, the amino acids contained either in peptides or proteins are named in a fashion related to that used for alkanes. The “-ine” suffix is replaced by “-yl” to give, for GAG, glycyl-alanyl-glycine. Peptide and protein sequences are always written and named from the N-terminus to the C-terminus. The C-terminal amino acid retains its full name.

Stereochemistry

Concepts in stereochemistry, that is, chemistry in three-dimensional space, are in the process of rapid expansion. This section will deal with only the main principles. The compounds discussed will be those that have identical molecular formulas but differ in the arrangement of their atoms in space. *Stereoisomers* is the name applied to these compounds.

Stereoisomers can be grouped into three categories: (1) Conformational isomers differ from each other only in the way their atoms are oriented in space, but can be converted into one another by rotation about sigma bonds. (2) Geometric isomers are compounds in which rotation about a double bond is restricted. (3) Configurational isomers differ from one another only in configuration about a chiral center, axis, or plane. In subsequent structural representations, a broken line denotes a bond projecting behind the plane of the paper and a wedge denotes a bond projecting in front of the plane of the paper. A line of normal thickness denotes a bond lying essentially in the plane of the paper.

Conformational Isomers. A molecule in a conformation into which its atoms return spontaneously after small displacements is termed a *conformer*. Different arrangements of atoms that can be converted into one another by rotation about single bonds are called *conformational isomers* (see Figure 1.3). A pair of conformational isomers can be but do not have to be mirror images of each other. When they are not mirror images, they are called *diastereomers*.

FIGURE 1.3 Eclipsed (left) and staggered (right) conformations of ethane. The ball and stick model is in the staggered conformation.

Acyclic Compounds. Different conformations of acyclic compounds are best viewed by construction of ball-and-stick molecules or by use of Newman projections. Both types of representations are shown for ethane. Atoms or groups that are attached at opposite ends of a single bond should be viewed along the bond axis. If two atoms or groups attached at opposite ends of the bond appear directly one behind the other, these atoms or groups are described as eclipsed. That portion of the molecule is described as being in the eclipsed conformation. If not eclipsed, the atoms or groups and the conformation may be described as staggered. Newman projections show these conformations clearly.

Certain physical properties show that rotation about the single bond is not quite free. For ethane there is an energy barrier of about $3\text{ kcal} \cdot \text{mol}^{-1}$ ($12\text{ kJ} \cdot \text{mol}^{-1}$). The potential energy of the molecule is at a minimum for the staggered conformation, increases with rotation, and reaches a maximum at the eclipsed conformation. The energy required to rotate the atoms or groups about the carbon-carbon bond is called *torsional energy*. Torsional strain is the cause of the relative instability of the eclipsed conformation or any intermediate skew conformations.

FIGURE 1.4 Conformations of butane. (a) *Anti*-staggered; (b) eclipsed; (c) *gauche*-staggered; (d) eclipsed; (e) *gauche*-staggered; (f) eclipsed. (Eclipsed conformations are slightly staggered for convenience in drawing; actually they are superimposed.)

In butane, with a methyl group replacing one hydrogen on each carbon of ethane, there are several different staggered conformations (see Figure 1.4). There is the *anti* conformation in which the methyl groups are as far apart as they can be (dihedral angle of 180°). There are two *gauche* conformations in which the methyl groups are only 60° apart; these are two nonsuperimposable mirror images of each other. The *anti* conformation is more stable than the *gauche* by about $0.9 \text{ kcal} \cdot \text{mol}^{-1}$ ($4 \text{ kJ} \cdot \text{mol}^{-1}$). Both are free of torsional strain. However, in a *gauche* conformation the methyl groups are closer together than the sum of their van der Waals' radii. Under these conditions van der Waals' forces are repulsive and raise the energy of conformation. This strain can affect not only the relative stabilities of various staggered conformations but also the heights of the energy barriers between them. The energy maximum (estimated at $4.8\text{--}6.1 \text{ kcal} \cdot \text{mol}^{-1}$ or $20\text{--}25 \text{ kJ} \cdot \text{mol}^{-1}$) is reached when two methyl groups swing past each other (the eclipsed conformation) rather than past hydrogen atoms.

Cyclic Compounds. Although cyclic aliphatic compounds are often drawn as if they were planar geometric figures (a triangle for cyclopropane, a square for cyclobutane, and so on), their structures are not that simple. Cyclopropane does possess the maximum angle strain if one considers the difference between a tetrahedral angle (109.5°) and the 60° angle of the cyclopropane structure. Nevertheless the cyclopropane structure is thermally quite stable. The highest electron density of the carbon–carbon bonds does not lie along the lines connecting the carbon atoms. Bonding electrons lie principally outside the triangular internuclear lines and result in what are known as *bent bonds* (see Figure 1.5).

Cyclobutane has less angle strain than cyclopropane (only 19.5°). It is also believed to have some bent-bond character associated with the carbon–carbon bonds. The molecule exists in a nonplanar conformation in order to minimize hydrogen–hydrogen eclipsing strain.

FIGURE 1.5 The bent bonds ("tear drops") of cyclopropane.

FIGURE 1.6 The conformations of cyclopentane.

FIGURE 1.7 The two chair conformations of cyclohexane: *a* = axial hydrogen atom and *e* = equatorial hydrogen atom. The middle and bottom panels show methylcyclohexane in the chair form with the methyl group equatorial (middle) and axial (bottom).

Cyclopentane is nonplanar, with a structure that resembles an envelope (see Figure 1.6). Four of the carbon atoms are in one plane, and the fifth is out of that plane. The molecule is in continual motion so that the out-of-plane carbon moves rapidly around the ring.

The 12 hydrogen atoms of cyclohexane do not occupy equivalent positions. In the chair conformation six hydrogen atoms are perpendicular to the average plane of the molecule and six are directed outward from the ring, slightly above or below the molecular plane (see Figure 1.7). Bonds which are perpendicular to the molecular plane are known as *axial bonds*, and those which extend outward from the ring are known as *equatorial bonds*. The three axial bonds directed upward originate from alternate carbon atoms and are parallel with each other; a similar situation exists for the three axial bonds directed downward. Each equatorial bond is drawn so as to be parallel with the ring carbon–carbon bond once removed from the point of attachment to that equatorial bond. At room temperature, cyclohexane is interconverting rapidly between two chair conformations. As one chair form converts to the other, all the equatorial hydrogen atoms become axial and all the axial hydrogens become equatorial. The interconversion is so rapid that all hydrogen atoms on cyclohexane can be considered equivalent. Interconversion is believed to take place by movement of one side of the chair structure to produce the twist boat, and then movement of the other side of the twist boat to give the other chair form. The chair conformation is the most favored structure for cyclohexane. No angle strain is encountered since all bond angles remain tetrahedral. Torsional strain is minimal because all groups are staggered.

In the boat conformation of cyclohexane (Figure 1.8) eclipsing torsional strain is significant, although no angle strain is encountered. Nonbonded interaction between the two hydrogen atoms across the ring from each other (the “flagpole” hydrogens) is unfavorable. The boat conformation is about $6.5 \text{ kcal} \cdot \text{mol}^{-1}$ ($27 \text{ kJ} \cdot \text{mol}^{-1}$) higher in energy than the chair form at 25°C .

FIGURE 1.8 The boat conformation of cyclohexane. *a* = axial hydrogen atom and *e* = equatorial hydrogen atom.

FIGURE 1.9 Twist-boat conformation of cyclohexane.

FIGURE 1.10 Two isomers of 1,4-dimethylcyclohexane. (a) *Trans* isomer; (b) *cis* isomer.

A modified boat conformation of cyclohexane, known as the twist boat (Figure 1.9), or skew boat, has been suggested to minimize torsional and nonbonded interactions. This particular conformation is estimated to be about $1.5 \text{ kcal} \cdot \text{mol}^{-1}$ (6 kJ mol^{-1}) lower in energy than the boat form at room temperature.

The medium-size rings (7–12 ring atoms) are relatively free of angle strain and can easily take a variety of spatial arrangements. They are not large enough to avoid all nonbonded interactions between atoms.

Disubstituted cyclohexanes can exist as *cis-trans* isomers as well as axial-equatorial conformers. Two isomers are predicted for 1,4-dimethylcyclohexane (see Figure 1.10). For the *trans* isomer the diequatorial conformer is the energetically favorable form. Only one *cis* isomer is observed, since the two conformers of the *cis* compound are identical. Interconversion takes place between the conformational (equatorial-axial) isomers but not configurational (*cis-trans*) isomers.

The bicyclic compound decahydronaphthalene, or bicyclo[4.4.0]decane, has two fused six-membered rings. It exists in *cis* and *trans* forms (see Figure 1.11), as determined by the configurations at the bridgehead carbon atoms. Both *cis*- and *trans*-decahydronaphthalene can be constructed with two chair conformations.

FIGURE 1.11 Two isomers of decahydronaphthalene, or bicyclo[4.4.0]decane. (a) *Trans* isomer; (b) *cis* isomer.

FIGURE 1.12 Two isomers of 2-butene. (a) *Cis* isomer, bp 3.8°C, mp -138.9°C, dipole moment 0.33 D; (b) *trans* isomer, bp 0.88°C, mp -105.6°C, dipole moment 0 D.

Geometrical Isomerism. Rotation about a carbon-carbon double bond is restricted because of interaction between the *p* orbitals which make up the pi bond. Isomerism due to such restricted rotation about a bond is known as *geometric isomerism*. Parallel overlap of the *p* orbitals of each carbon atom of the double bond forms the molecular orbital of the pi bond. The relatively large barrier to rotation about the pi bond is estimated to be nearly 63 kcal · mol⁻¹ (263 kJ · mol⁻¹).

When two different substituents are attached to each carbon atom of the double bond, *cis-trans* isomers can exist. In the case of *cis*-2-butene (Figure 1.12a), both methyl groups are on the same side of the double bond. The other isomer has the methyl groups on opposite sides and is designated as *trans*-2-butene (Figure 1.12b). Their physical properties are quite different. Geometric isomerism can also exist in ring systems; examples were cited in the previous discussion on conformational isomers.

For compounds containing only double-bonded atoms, the reference plane contains the double-bonded atoms and is perpendicular to the plane containing these atoms and those directly attached to them. It is customary to draw the formulas so that the reference plane is perpendicular to that of the paper. For cyclic compounds the reference plane is that in which the ring skeleton lies or to which it approximates. Cyclic structures are commonly drawn with the ring atoms in the plane of the paper.

Sequence Rules for Geometric Isomers and Chiral Compounds. Although *cis* and *trans* designations have been used for many years, this approach becomes useless in complex systems. To eliminate confusion when each carbon of a double bond or a chiral center is

FIGURE 1.13 Configurations designated by priority groups. (a) *Z* (*cis*); (b) *E* (*trans*).

connected to different groups, the Cahn, Ingold, and Prelog system for designating configuration about a double bond or a chiral center has been adopted by IUPAC. Groups on each carbon atom of the double bond are assigned a first (1) or second (2) priority. Priority is then compared at one carbon relative to the other. When both first priority groups are on the *same side* of the double bond, the configuration is designated as *Z* (from the German *zusammen*, “together”), which was formerly *cis*. If the first priority groups are on *opposite sides* of the double bond, the designation is *E* (from the German *entgegen*, “in opposition to”), which was formerly *trans*. (See Figure 1.13.)

When a molecule contains more than one double bond, each *E* or *Z* prefix has associated with it the lower-numbered locant of the double bond concerned. Thus (see also the rules that follow)

When the sequence rules permit alternatives, preference for lower-numbered locants and for inclusion in the principal chain is allotted as follows in the order stated: *Z* over *E* groups and *cis* over *trans* cyclic groups. If a choice is still not attained, then the lower-numbered locant for such a preferred group at the first point of difference is the determining factor. For example,

RULE 1. Priority is assigned to atoms on the basis of atomic number. Higher priority is assigned to atoms of higher atomic number. If two atoms are isotopes of the same element, the atom of higher mass number has the higher priority. For example, in 2-butene, the carbon atom of each methyl group receives first priority over the hydrogen atom connected to the same carbon atom. Around the asymmetric carbon atom in chloriodomethanesulfonic acid, the priority sequence is I, Cl, S, H. In 1-bromo-1-deuteroethane, the priority sequence is Cl, C, D, H.

RULE 2. When atoms attached directly to a double-bonded carbon have the same priority, the second atoms are considered and so on, if necessary, working outward once again from the double bond or chiral center. For example, in 1-chloro-2-methylbutene, in CH_3 the second atoms are H, H, H and in CH_2CH_3 they are C, H, H. Since carbon has a higher atomic number than hydrogen, the ethyl group has the next highest priority after the chlorine atom.

RULE 3. When groups under consideration have double or triple bonds, the multiple-bonded atom is replaced conceptually by two or three single bonds to that same kind of

atom. Thus, $=\text{A}$ is considered to be equivalent to two A's, or $\begin{array}{c} \text{A} \\ \diagdown \quad \diagup \\ \text{C} \\ \diagup \quad \diagdown \\ \text{A} \end{array}$ and $\equiv\text{A}$ equals $\begin{array}{c} \text{A} \\ \diagdown \quad \diagup \\ \text{C} \\ \diagup \quad \diagdown \\ \text{A} \end{array}$.

However, a real $\begin{array}{c} \text{A} \\ \diagdown \quad \diagup \\ \text{C} \\ \diagup \quad \diagdown \\ \text{A} \end{array}$ has priority over $=\text{A}$; likewise a real $\begin{array}{c} \text{A} \\ \diagdown \quad \diagup \\ \text{C} \\ \diagup \quad \diagdown \\ \text{A} \end{array}$ has priority over $\equiv\text{A}$.

Actually, both atoms of a multiple bond are duplicated, or triplicated, so that $\text{C}=\text{O}$ is

treated as $\begin{array}{c} \text{C}-\text{O} \\ | \quad | \\ \text{O} \quad \text{C} \end{array}$, that is $\begin{array}{c} \text{C}-\text{O} \\ | \\ (\text{O}) \end{array}$ and $\begin{array}{c} \text{O}-\text{C} \\ | \\ (\text{C}) \end{array}$, and $\text{C}\equiv\text{N}$ is treated as

$\begin{array}{c} \text{C} \quad \text{N} \\ \diagdown \quad \diagup \quad \diagdown \quad \diagup \\ (\text{N}) \quad (\text{N}) \quad (\text{C}) \quad (\text{C}) \end{array}$. A phenyl carbon becomes $\begin{array}{c} \text{CH} \\ \diagdown \quad \diagup \\ \text{C}-\text{C} \\ \diagup \quad \diagdown \\ \text{CH} \end{array}$. Only the double-bonded

atoms themselves are duplicated, not the atoms or groups attached to them. The duplicated atoms (or phantom atoms) may be considered as carrying atomic number zero. For example, among the groups OH, CHO, CH_2OH , and H, the OH group has the highest priority, and the C(O, O, H) of CHO takes priority over the C(O, H, H) of CH_2OH .

Chirality and Optical Activity. A compound is chiral (the term *dissymmetric* was formerly used) if it is not superimposable on its mirror image. A chiral compound does not have a plane of symmetry. Each chiral compound possesses one (or more) of three types of chiral element, namely, a chiral center, a chiral axis, or a chiral plane.

Chiral Center. The chiral center, which is the chiral element most commonly met, is exemplified by an asymmetric carbon with a tetrahedral arrangement of ligands about the carbon. The ligands comprise four different atoms or groups. One "ligand" may be a lone pair of electrons; another, a phantom atom of atomic number zero. This situation is encountered in sulfoxides or with a nitrogen atom. Lactic acid is an example of a molecule with an asymmetric (chiral) carbon. (See Figure 1.14.)

A simpler representation of molecules containing asymmetric carbon atoms is the Fischer projection, which is shown here for the same lactic acid configurations. A Fischer

FIGURE 1.14A Stereo drawing of the lactic acid molecule.

FIGURE 1.14B Fischer projection of the lactic acid molecule.

projection involves drawing a cross and attaching to the four ends the four groups that are attached to the asymmetric carbon atom. The asymmetric carbon atom is understood to be located where the lines cross. The horizontal lines are understood to represent bonds coming toward the viewer out of the plane of the paper. The vertical lines represent bonds going away from the viewer behind the plane of the paper as if the vertical line were the side of a circle. The principal chain is depicted in the vertical direction; the lowest-numbered (locant) chain member is placed at the top position. These formulas may be moved sideways or rotated through 180° in the plane of the paper, but they may not be removed from the plane of the paper (i.e., rotated through 90°). In the latter orientation it is essential to use thickened lines (for bonds coming toward the viewer) and dashed lines (for bonds receding from the viewer) to avoid confusion.

Enantiomers. Two nonsuperimposable structures that are mirror images of each other are known as *enantiomers*. Enantiomers are related to each other in the same way that a right hand is related to a left hand. Except for the direction in which they rotate the plane of polarized light, enantiomers are identical in all physical properties. Enantiomers have identical chemical properties except in their reactivity toward optically active reagents.

Enantiomers rotate the plane of polarized light in opposite directions but with equal magnitude. If the light is rotated in a clockwise direction, the sample is said to be dextro-rotatory and is designed as (+). When a sample rotates the plane of polarized light in a counterclockwise direction, it is said to be levorotatory and is designed as (−). Use of the designations *d* and *l* is discouraged.

Specific Rotation. Optical rotation is caused by individual molecules of the optically active compound. The amount of rotation depends upon how many molecules the light beam encounters in passing through the tube. When allowances are made for the length of the tube that contains the sample and the sample concentration, it is found that the amount of rotation, as well as its direction, is a characteristic of each individual optically active compound.

Specific rotation is the number of degrees of rotation observed if a 1-dm tube is used and the compound being examined is present to the extent of 1 g per 100 mL. The density for a pure liquid replaces the solution concentration.

$$\text{Specific rotation} = [\alpha] = \frac{\text{observed rotation (degrees)}}{\text{length (dm)} \times (\text{g}/100 \text{ mL})}$$

The temperature of the measurement is indicated by a superscript and the wavelength of the light employed by a subscript written after the bracket; for example, $[\alpha]_{590}^{20}$ implies that the measurement was made at 20°C using 590 nm radiation.

Optically Inactive Chiral Compounds. Although chirality is a necessary prerequisite for optical activity, chiral compounds are not necessarily optically active. With an equal mixture of two enantiomers, no net optical rotation is observed. Such a mixture of enantiomers is said to be *racemic* and is designated as (\pm) and not as *dl*. Racemic mixtures usually have melting points higher than the melting point of either pure enantiomer.

A second type of optically inactive chiral compounds, *meso* compounds, will be discussed next.

Multiple Chiral Centers. The number of stereoisomers increases rapidly with an increase in the number of chiral centers in a molecule. A molecule possessing two chiral atoms should have four optical isomers, that is, four structures consisting of two pairs of enantiomers. However, if a compound has two chiral centers but both centers have the same four substituents attached, the total number of isomers is three rather than four. One isomer of such a compound is not chiral because it is identical with its mirror image; it has an internal mirror plane. This is an example of a diastereomer. The achiral structure is denoted as a *meso* compound. Diastereomers have different physical and chemical properties from the optically active enantiomers. Recognition of a plane of symmetry is usually the easiest way to detect a *meso* compound. The stereoisomers of tartaric acid are examples of compounds with multiple chiral centers (see Figure 1.15), and one of its isomers is a *meso* compound.

Stereochemistry is sometimes harder to discern in ring systems than in open-chained compounds. The smallest ring, cyclopropane, has six equivalent hydrogens, each of which may be substituted. When a substituent such as a methyl group replaces a hydrogen, the molecule remains achiral because a mirror plane is present that bisects the substituted carbon (and its substituent) and the opposite bond. One side of the cyclopropane therefore reflects the other. The presence of a substituent makes the other cyclopropane positions nonequivalent. Thus a second methyl group may be added on the same carbon (opposite side of the ring) or on one of the adjacent carbons on either the same or opposite sides of the ring. Figure 1.16 shows some of these possibilities. *E*-1,2-Dicarboxycyclopropane (a) exists in two distinct forms. They are nonsuperimposable mirror images; *Z*-1,2-Dicarboxycyclopropane (b) has an internal mirror plane and is therefore superimposable on its mirror image. Structure (d) in Figure 1.16 shows a molecular model of this compound. The carboxyl substituents do not appear to reflect each other but recall that they can rotate freely about the single bond.

A cyclic compound that has two differently substituted asymmetric carbons will have $2^2 = 4$ optical isomers. These will consist of pairs of *cis* and *trans* enantiomers. When the asymmetric centers have identical substituents, the *cis* isomer will have an internal reflection plane and is called a *meso* form. The *meso* forms of *cis*-1,2-dicarboxycyclopropane are shown in panels (b) and (d) of Figure 1.16 in a line angle drawing and as a molecular model.

Torsional Asymmetry. Rotation about single bonds of most acyclic compounds is relatively free at ordinary temperatures. There are, however, some examples of compounds in which nonbonded interactions between large substituent groups inhibit free rotation about a sigma bond. In some cases these compounds can be separated into pairs of enantiomers.

FIGURE 1.15 Isomers of tartaric acid.

FIGURE 1.16 Isomers of cyclopropane-1,2-dicarboxylic acid. (a) *E*-1,2-Dicarboxycyclopropane (*trans* isomers); (b) *Z*-1,2-Dicarboxycyclopropane isomer. (*meso* isomer); (c) Molecular models of *E*- (*trans*-) 1,2-dimethylcyclopropane shown in the tube representation. Rotation of the right hand structure about a vertical axis through the center of the cyclopropane will superimpose the two methyl groups. The methylene of the rotated structure will be in the back, rather than the front, and not superimposed. (d) A mirror plane through the methylene and the back carbon-carbon bond is a plane of symmetry. The two carboxyl groups appear not to reflect each other in the model shown but they can rotate freely and will reflect each other on an instantaneous basis.

A *chiral axis* is present in chiral biaryl derivatives. When bulky groups are located at the *ortho* positions of each aromatic ring in biphenyl, free rotation about the single bond connecting the two rings is inhibited because of torsional strain associated with twisting rotation about the central single bond. Interconversion of enantiomers is prevented (see Figure 1.17).

FIGURE 1.17 Isomers of biphenyl compounds with bulky groups attached at the *ortho* positions.

For compounds possessing a chiral axis, the structure can be regarded as an elongated tetrahedron to be viewed along the axis. In deciding upon the absolute configuration it does not matter from which end it is viewed; the nearer pair of ligands receives the first two positions in the order of precedence (see Figure 1.18). For the meaning of (*S*), see the discussion under "Absolute Configuration".

A *chiral plane* is exemplified by the plane containing the benzene ring and the bromine and oxygen atoms in the chiral compound shown in Figure 1.19. Rotation of the benzene ring around the oxygen-to-ring single bonds is inhibited when x is small (although no critical size can be reasonably established).

FIGURE 1.18 Example of a chiral axis.

FIGURE 1.19 Example of a chiral plane.

Absolute Configuration. The terms absolute stereochemistry and absolute configuration are used to describe the three-dimensional arrangement of substituents around a chiral element. A general system for designating absolute configuration is based upon the priority system and sequence rules. Each group attached to a chiral center is assigned a number, with number one the highest-priority group. For example, the groups attached to the chiral center of 2-butanol (see Figure 1.20) are assigned these priorities: 1 for OH, 2 for CH_2CH_3 , 3 for CH_3 , and 4 for H. The molecule is then viewed from the side opposite the group of lowest priority (the hydrogen atom), and the arrangement of the remaining groups are noted. If, in proceeding from the group of highest priority to the group of second priority and

FIGURE 1.20 Viewing angle as a means of designating the absolute configuration of compounds with a chiral axis. (a) (*R*)-2-butanol (sequence clockwise); (b) (*S*)-2-butanol (sequence counterclockwise).

thence to the third, the eye travels in a clockwise direction, the configuration is specified *R* (from the Latin *rectus*, “right”); if the eye travels in a counterclockwise direction, the configuration is specified *S* (from the Latin *sinister*, “left”). The complete name includes both configuration and direction of optical rotation, as for example, (*S*)-(+)-2-butanol.

The relative configurations around the chiral centers of many compounds have been established. One optically active compound is converted to another by a sequence of chemical reactions which are stereospecific; that is, each reaction is known to proceed spatially in a specific way. The configuration of one chiral compound can then be related to the configuration of the next in sequence. In order to establish absolute configuration, one must carry out sufficient stereospecific reactions to relate a new compound to another of known absolute configuration. Historically the configuration of D-(+)-2,3-dihydroxypropanal has served as the standard to which all configuration has been compared. The absolute configuration assigned to this compound has been confirmed by an X-ray crystallographic technique.

Stereochemistry in Biological Systems. Amino acids occur naturally in both D and L (*R* and *S*) enantiomeric configurations. Amino acids that occur in proteins almost always have the L configuration although amino acids that occur in bacterial peptides may have the enantiomeric D configuration. The two configurations are shown in Figure 1.21 for alanine.

The description of α -amino acids as D or L is a holdover from an older nomenclature system. In this system (*S*)-alanine is called L-alanine. The enantiomer would be D- or (*R*)-serine. The L (*laevo*, turned to the left; D = *dextro*, turned to the right) designation refers to the α -carbon in the essential amino acids. In alanine, there is a single α -carbon that is asymmetric. When two asymmetric centers are present as in L-threonine, the stereochemistry of both carbons must be considered. The common form of L-threonine is the 2*S*,3*R* stereoisomer.

Threonine (center) is shown in Figure 1.22 along with the simplest chiral amino acid, alanine. The only cyclic amino acid, proline, is pictured as well in the common L-configuration.

Extended Arrangements of Peptides and Proteins. Amino acids are linked from the carboxyl to the amine with formation of an amide bond, often referred to as the peptide link. The repeating ($-\text{N}-\text{C}-\text{CO}-$) unit is called the peptide or protein backbone. Peptides and proteins differ only in the number of amino acids present in the biopolymer chain. The cutoff is arbitrarily set. Often, but not always, a peptide is designated as having fewer than 100 amino acids and the protein possesses more. Backbone amide groups have been found to play a role in enzyme catalysis.

FIGURE 1.21 Stereochemistry of α -amino acids. The most common, L configuration is shown at the left.

FIGURE 1.22 Structures of alanine, threonine, and proline.

The extended chains, that is, the backbones, may further organize into assemblies that have characteristic properties. The two most important of these are the α -helix and the β -sheet. The latter is illustrated in Figure 1.23. Panel (a) shows the extensive hydrogen bond organization of peptide chains that are oriented in opposite directions. The arrows indicate the nitrogen to carbonyl (arrowhead) direction. The lower panel (b) shows an alternate H-bond organization when the two peptide chains are parallel rather than antiparallel.

FIGURE 1.23 Hydrogen bonded interactions of peptide chains to form β -sheets. The chains are arranged antiparallel in panel (a) and parallel in panel (b).

An alternate organization for peptide chains is the α -helix. It is essentially a coil in which a carbonyl group H-bonds an amide nitrogen between every fourth residue. The resulting structure exhibits one full turn for each 3.6 amino acids, which spans 5.4 Å per turn. The resulting α -helix is a tight coil that lacks any significant interior space. A schematic representation of the H-bonded coil is shown in Figure 1.24.

FIGURE 1.24

A number of other arrangements are possible for peptide or protein chains. A discussion of them is beyond the scope of this Handbook.

Chemical Abstracts Indexing System

When compounds of complex structure are considered, the number of name possibilities grows rapidly. To avoid having index entries for all possible names, Chemical Abstracts Service has developed what might be called the principle of inversion. The indexing system employs inverted entries to bring together related compounds in an alphabetically arranged index. The *index heading parent* from the Chemical Substance Index appears in the Formula Index in lightface before the “comma of inversion.” The *substituents* follow the “comma of

inversion" in alphabetical order. Any *name modification* appears on a separate line. If necessary, the chemical description is completed by citation of an associated ion, a functional derivative, a "salt with" or "compound with" terms and/or a stereochemical descriptor.

Quite naturally there is a certain amount of arbitrariness in this system, although the IUPAC nomenclature is followed. The preferred *Chemical Abstracts* index names for chemical substances have been, with very few exceptions, continued unchanged (since 1972) as set forth in the *Ninth Collective Index Guide* and in a journal article.* Any revisions appear in the updated *Index Guide*; new editions appear at 18-month intervals. Appendix VI is of particular interest to chemists. Reprints of the Appendix may be purchased from Chemical Abstracts Service, Marketing Division, P.O. Box 3012, Columbus, Ohio 43210.

TABLE 1.15 Physical Constants of Organic Compounds*See also the special tables of fats, oils, and waxes.*

Names of the compounds in the table starting on p. 1.82 are arranged alphabetically. Usually substitutive nomenclature is employed; exceptions generally involve ethers, sulfides, sulfones, and sulfoxides. Each compound is given a number within its letter classification; thus compound c195 is 3-chlorophenol. The section "Nomenclature of Organic Compounds" should be consulted to familiarize oneself with present nomenclature systems.

Synonyms or *Alternate Names* are found at the bottom of each spread in their alphabetical listing; the number following the name refers to the numerical place of this compound in the table. For example, epichlorohydrin, c101, indicates that this compound is found listed under the name 1-chloro-2,3-epoxypropane.

Formulas are presented in a semistructural form when no ambiguity is possible. Complicated systems are drawn in complete structural form and located at the bottom of each page and keyed to the number of the entry.

Beilstein Reference. In the column so headed is found the reference to the volume and page numbers of the fourth edition of Beilstein: (Handbuch der Organischen Chemie) (Springer-Verlag, New York). Thus the entry 9, 202 refers to an entry in volume 9 appearing on page 202. When the volume number has a superscript attached, reference is made to the appropriate supplementary volume. For example, 12², 404 indicates that the compound will be found listed in the second supplement to volume 12 on page 404. The earliest Beilstein entry is listed. Supplementary information may be found in the supplements to the basic series; such coordinating references (series number, volume number, and page number of the main edition) along with the system number are found at the top of each *odd-numbered* page. Similarly, a back reference such as H 93; E II 64; E III 190 in a volume of Supplementary Series IV means that previous items on

TABLE 1.15 Physical Constants of Organic Compounds*See also the special tables of fats, oils, and waxes.*

Names of the compounds in the table starting on p. 1.82 are arranged alphabetically. Usually substitutive nomenclature is employed; exceptions generally involve ethers, sulfides, sulfones, and sulfoxides. Each compound is given a number within its letter classification; thus compound c195 is 3-chlorophenol. The section "Nomenclature of Organic Compounds" should be consulted to familiarize oneself with present nomenclature systems.

Synonyms or *Alternate Names* are found at the bottom of each spread in their alphabetical listing; the number following the name refers to the numerical place of this compound in the table. For example, epichlorohydrin, c101, indicates that this compound is found listed under the name 1-chloro-2,3-epoxypropane.

Formulas are presented in a semistructural form when no ambiguity is possible. Complicated systems are drawn in complete structural form and located at the bottom of each page and keyed to the number of the entry.

Beilstein Reference. In the column so headed is found the reference to the volume and page numbers of the fourth edition of Beilstein: (Handbuch der Organischen Chemie) (Springer-Verlag, New York). Thus the entry 9, 202 refers to an entry in volume 9 appearing on page 202. When the volume number has a superscript attached, reference is made to the appropriate supplementary volume. For example, 12², 404 indicates that the compound will be found listed in the second supplement to volume 12 on page 404. The earliest Beilstein entry is listed. Supplementary information may be found in the supplements to the basic series; such coordinating references (series number, volume number, and page number of the main edition) along with the system number are found at the top of each *odd-numbered* page. Similarly, a back reference such as H 93; E II 64; E III 190 in a volume of Supplementary Series IV means that previous items on

this compound are found in the same volume of the Basic Series on page 93, of Supplementary Series II on page 64, and of Supplementary Series III on page 190. The absence of a back reference implies that the compound involved is described *for the first time* in the series concerned.

Formula Weights are based on the International Atomic Weights of 1973 and are computed to the nearest hundredth.

Density values are given at room temperature unless otherwise indicated by the superscript figure; thus 0.9711¹¹² indicates a density of 0.9711 for the substance at 112°C. A density of 0.899₄¹⁶ indicates a density of 0.899 for the substance at 16°C relative to water at 4°C.

Refractive Index, unless otherwise specified, is given for the sodium line at 589.6 nm. The temperature at which the measurement was made is indicated by the superscript figure; otherwise it is assumed to be room temperature.

Melting Point is recorded in certain cases as 250 d and in some other cases as d 250, the distinction being made in this manner to indicate that the former is a melting point with decomposition at 250°C, while the latter decomposition occurs only at 250°C and higher temperatures. Where a value such as -2H₂O, 120 is given, it indicates a loss of 2 mol of water per formula weight of the compound at a temperature of 120°C.

Boiling Point is given at atmospheric pressure (760 mmHg) unless otherwise indicated; thus 82¹⁵ mm indicates that the boiling point is 82°C when the pressure is 15 mmHg. Also, subl 550 indicates that the compound sublimes at 550°C.

Flash Point is given in degrees Celsius, usually closed up. Because values will vary with the specific procedure employed, and sometimes the method was not stated, the values listed for the flash point should be considered only as indicative. See also Table 4.13, Properties of Combustible Mixtures in Air.

Solubility is given in parts by weight (of the formula weight) per 100 parts by weight of the solvent and at room temperature. Other temperatures are indicated by the superscript. In the case of gases, the solubility is often expressed as 5¹⁰ mL, which indicates that at 10°C, 5 mL of the gas is soluble in 100 g of the solvent.

Abbreviations Used in the Table

abs, absolute	EtOH, ethanol, 95%	s, soluble
acet, acetone	expl, explodes	sec, secondary
alc, ethanol	glyc, glycerol	sl, slight or slightly
alk, alkali (i.e., aqueous NaOH or KOH)	h, hot	soln, solution
anhyd, anhydrous	HOAc, acetic acid	solv, solvent
aq, aqueous; water	hyd, hydrolysis	subl, sublimes
as, asymmetrical	hygr, hygroscopic	s, symmetrical
atm, atmosphere	i, insoluble	sym, symmetrical
BuOH, butanol	ign, ignites	tert, tertiary
bz, benzene	i-PrOH, isopropanol	v, very
c, cold	l (-), levorotatory	v s, very soluble
chl, chloroform, CHCl ₃	L, designates configuration	v sl s, very slightly soluble
conc, concentrated	m, meta position	vac, vacuo or vacuum
d, decomposes or decomposed	Me, methyl	vols, volumes
d (+), dextrorotatory	MeEtKe, methyl ethyl ketone	>, greater than
-d ₂ , deuterium substitution	MeOH, methanol	<, less than
D, designates configuration	misc, miscible; soluble in all proportions	~, approximately
deliq, deliquescent	NaOH, aqueous sodium hydroxide	α, alpha position
dil, dilute	o, ortho position	β, beta position
diox, dioxane	org, organic	γ, gamma position
DL (or dl), inactive (i.e., 50% D and 50% L)	p, para position	δ, delta position
DMF, dimethylformamide	PE, petroleum ether	ε, epsilon position
EtAc, ethyl acetate	pyr, pyridine	ω, omega position (farthest from parent functional group)
eth, diethyl ether

SECTION 2

INORGANIC AND ORGANOMETALLIC COMPOUNDS

Table 2.1 Physical Constants of Inorganic Compounds	2.2
---	-----

This section summarizes the properties of various chemical compounds commonly encountered in organic chemistry that are often referred to either as inorganic or organometallic. In some cases, the distinction is artificial and the reader should refer to Section 1 if the expected compound is not presented here. Most compounds containing metals are collected here, rather than in Section 1.

TABLE 2.1 Physical Constants of Inorganic Compounds

Explanation of column headings

Names, while following the IUPAC nomenclature, are generally alphabetized by the central atom to facilitate their location. An example of the table organization is given below for Al_3C_4 , aluminum tetracarbide. It is entered in Table 2.1 as follows:

Main heading	Aluminum
<i>Subgrouping</i>	carbide
Actual table listing	Aluminum (tetra-) carbide (tri-)

Solvates are listed under the entry for the anhydrous salt. Hydrazine hydrate, $\text{H}_2\text{N}-\text{NH}_2\cdot\text{H}_2\text{O}$ is listed under hydrazine. Magnesium sulfate heptahydrate (epsom salt) is listed under **Magnesium**, using the subgroup sulfate 7-water. Inorganic acids are entered under hydrogen. For example, HF is listed under **Hydrogen**, using the subgroup fluoride. Where an elemental designation would be confusing or inappropriate, the compound is listed alphabetically as in the case of **hydroxylamine**, HONH_2 .

Abbreviations used in the Table

>, greater than	ca, approximately	g, gas	pyr, pyridine
α , alpha position	chl, chloroform	glyc, glycerol	s, soluble
a, acid	conc, concentrated	h, hot	satd, saturated
abs, absolute	cub, cubic	hex, hexagonal	sl, slightly
acetone, acet	d, decompose(s)	hyd, hydrolysis	soln, solution
alc, alcohol	dil, dilute	i, insoluble	solv, solvent(s)
alk, alkali, (aq NaOH)	DMF,	ign, ignites	subl, sublimates
anhyd, anhydrous	dimethylformamide	lq, liquid	tetr, tetragonal
aq, aqueous	eth, diethyl ether	MeOH, methanol	THF, tetrahydrofuran
aq reg, aqua regia	EtOH, ethanol	min, mineral	tr, transition
atm, atmosphere	expl, explodes,	misc, miscible	v, very
bz, benzene	explosive	org, organic	vac, <i>vacuo</i> or vacuum
c, solid state	fcc, face-centered cubic	PE, petroleum ether	viol, violently

Formula Weights are based on the International Atomic Weights of 1973 and are computed to the nearest hundredth of an a.m.u.

Density values are given at room temperature unless otherwise indicated by a superscript figure indicating a temperature in $^{\circ}\text{C}$. Thus, 2.487^{15} indicates a density of 2.487 for the named substance at 15°C . For gases density values are given in grams per liter ($\text{g}\cdot\text{L}^{-1}$).

Melting Point values are recorded in $^{\circ}\text{C}$. In certain cases decomposition is indicated with the letter “d” that either precedes or follows the number. The value 250d indicates that the substance melts at 250°C with decomposition. The value d 250 indicates that decomposition only occurs at 250°C and higher temperatures. Where a value such as “ $-6\text{H}_2\text{O}$, 150” is given, it indicates a loss of 6 moles of water per formula weight of the compound at a temperature of 150°C .

Boiling Point values are given at atmospheric pressure (760 mm of mercury) unless otherwise indicated; a value of 82 means that the boiling point is 82°C at 760 mm Hg. A value of 82^{15} means that the boiling point is 82°C when the pressure is 15 mmHg. The specification “subl 550” indicates that the compound sublimates at 550°C .

Solubility is given in parts by weight (of the formula weight) per 100 parts by weight of the solvent. If the solvent is unspecified, it is water. If no temperature is specified, the solubility is for the substance at room temperature. Other temperatures (in $^{\circ}\text{C}$) are indicated by superscript. The symbols of the common mineral acids represent aqueous solutions of those acids.

TABLE 2.1 Physical Constants of Inorganic Compounds

Name	Formula	Formula weight	Density	Melting point, °C	Boiling point, °C	Solubility in 100 parts solvent

NUCLIDES

TABLE 3.1 Table of Nuclides

Explanation of column headings

Nuclide. Each nuclide is identified by its atomic number Z , equal to the number of protons in the nucleus; the corresponding symbol for that element; and the mass number A , equal to the sum of the numbers of protons Z and neutrons N in the nucleus. Thus, $A = Z + N$, or $N = A - Z$. The m following the mass number (e.g., ^{69m}Zn) indicates an isomer of that nuclide.

Half-Life. For the radioactive nuclides this time period corresponds to that during which loss by disintegration of 50% of the nuclide occurs. The units of time are designated by year (yr), day (d), hour (h), minute (min), and second (s).

Natural Abundance. The isotopic abundances listed are on an “atom percent” basis for the stable nuclides present in naturally occurring elements in the earth’s crust.

Thermal Neutron Absorption Cross Section. The ease with which a given nuclide can absorb a thermal neutron (energy $\leq \frac{1}{40}$ eV) and become of a different nuclide is indicated by the cross section, given here in units of barns (1 barn = 10^{-24} cm²). If the mode of reaction is other than (n, γ), it is so indicated, for example, (n, p) or (n, α), where n = neutron, p = proton, γ = gamma ray, and α = alpha particle (^4_2He).

Major Radiations. In this column are listed the principal mode(s) of decay and the energies of the emanating radiations in million electronvolts (MeV). The gamma-ray (γ) intensities, where given, are given to the nearest whole percentage in parentheses following the numerical energy value for that particular γ . In most cases the radiations listed should be sufficient for identification of the particular nuclide. The following designations are used: negatron (β^-), positron (β^+), conversion electron (e^-), gamma ray (γ), and alpha particle (α).

Nuclide		Half-life	Natural abundance, %	Thermal neutron absorption cross section, barns	Major radiations

ELECTRONEGATIVITY

According to Pauling, electronegativity χ is the relative attraction of an atom for the valence electrons in a covalent bond. It is proportional to the effective nuclear charge and inversely proportional to the covalent radius.

$$\chi = \frac{0.31(n + 1 \pm c)}{r} + 0.50$$

where n is the number of valence electrons, c is any formal valence charge on the atom and the sign before it corresponds to the sign of this charge, and r is the covalent radius. Because electronegativity is concerned with atoms in molecules rather than atoms in isolation, it is not possible to define precise electronegativity values. Pauling determined his set of values from bond energy data based on experimentally measured heats of dissociation and formation. Originally the element fluorine, whose atoms have the greatest attraction for electrons, was given an arbitrary electronegativity of 4.0. A revision of Pauling's values based on newer heat data assigns 3.9 to fluorine. A unit positive charge changes the χ value for an atom by about two-thirds of the electronegativity difference between it and the atom next on its right in the Periodic Table, and a unit negative charge similarly decreases the χ value.

The greater the difference in electronegativity, the greater is the ionic character of the bond. The amount of ionic character I is given by the expression

$$I = 1 - e^{-0.25(\chi_A - \chi_B)^2}$$

The bond is fully covalent when $(\chi_A - \chi_B) < 0.5$ (and $I < 6\%$). A different expression was proposed by Hannay-Smyth.*

$$I = 0.46|\chi_A - \chi_B| + 0.035(\chi_A - \chi_B)^2$$

Other sets of electronegativities of the elements have been proposed. The rather direct, but somewhat limited, method of Mulliken makes use of the ionization potential IP and electron-affinity data (Table 3.3). Numerical values are obtained that coincide with values from other methods if electronegativities are calculated from

$$\chi = \frac{IP + A}{5.6}$$

Electronegativities on the Allred-Rochow scale[†] are given by

$$\chi = 0.359 \frac{Z_{\text{eff}}}{r^2} + 0.744$$

where Z_{eff} is the effective nuclear charge and r is the atomic radius.

Using Pauling's values, electronegativities of the elements are arranged in periodic order in Table 3.2A.

* Hannay-Smyth, *J. Am. Chem. Soc.*, **68**: 171 (1946).

† *J. Inorg. Nucl. Chem.*, **5**: 264, 269 (1958).

				SH	2.8

Electronegativities have important uses in chemistry in addition to predicting the amount of ionic character in a bond. The bond stretching force constant k (in units of 10^5 dynes · cm^{−1}) can be estimated for stable molecules exhibiting their normal covalences by the expression:

$$k = 1.67 N \left(\frac{\chi_A \chi_B}{d^2} \right)^{3/4} + 0.30$$

where N is the bond order (i.e., the effective number of covalent or ionic bonds acting between the two atoms A and B) and d is the internuclear distance in angstroms.

An estimate of the percent ionic character may be made for organometallic compounds of the type alkyl-metal for metals in common use in organic synthesis. Among the alkali metals (row 1 of the Periodic Table, these are Li (43%), Na (47%), and K (51%)). The percent ionic character for an organomagnesium compound (typically a Grignard reagent), the bond is estimated to be 34% ionic. The more covalent organozinc and organocadmium compounds have correspondingly less ionic character: Zn (18%) and Cd (15%).

Electronegativities have also been estimated for various common substituent groups. They are arranged in Table 3.2B in clusters of related residues. The values for the individual halogens are from Table 3.2A.

Electronegativity is proportional to the work function ϕ , which is the energy necessary to just remove an electron from the metal surface in thermoelectric or photoelectric emission.

$$\chi = 0.44\phi - 0.15$$

ELECTRON AFFINITY

The *electron affinity* of an atom A is defined as the energy released when an atom and an electron react to form a negative ion in the gas phase at 0 K.

An example is the capture of an electron by chlorine to give chloride anion.

Conceptually related to this is the *ionization potential*, which is the energy for the process

An example is the loss of an electron by an alkali metal to give the alkali metal cation.

The second ionization potential carried this process further, that is, $A^+ \rightarrow A^{2+} + e^-$ and so on for the third or more ionization potentials. Both electron affinities and ionization potentials are typically expressed in electron volts (eV). Data for electron affinities are given in Table 3.3. Uncertainty in the final data figures is given in parentheses.

Source: H. Hotop and W. C. Lineberger, *J. Phys. Chem. Ref. Data*, **4**: 539 (1975). Data for ionization potentials are available in C. E. Moore, *National Bureau of Standards U. S. Publication NSRDS-NBS*, **34** (1970).

BOND LENGTHS AND STRENGTHS

The bonds most commonly encountered in organic chemistry are those between carbons and between carbon and heteroatoms of the first row of the Periodic Table. Generally and very approximately, single bonds between two carbon atoms are about 1.5 Å in length and have strengths near to, but usually less than, 100 kcal/mole (418 kJ/mol). Likewise, carbon–carbon double bonds are stronger (~150 kcal/mol) and shorter (~1.35 Å). Triple bonds are shorter still (C≡C ≈ 1.2 Å, ~200 kcal/mol). Bonds between carbon and either nitrogen or oxygen are somewhat shorter owing to the heteroatom's electronegativity. A few general examples are shown below and detailed data may be found in the Table 3.4.

General Trends in the Length of Common Organic Chemical Bonds

Bond	Length (Å)	Bond	Length (Å)	Bond	Length (Å)
C—C	1.54	C—O	1.43	H—C(sp ³)	1.12
C=C	1.33	C=O	1.20	N—H	1.03
C≡C	1.21	C—N	1.47	O—H	0.97
		C=N	1.28	C—Cl	1.76
		C≡N	1.15		

TABLE 3.4A Bond Lengths between Carbon and other Elements

The numbers in parentheses following a numerical value represent the standard deviation of that value in terms of the final listed digit.
To convert the bond length from angstroms into nanometers, multiply by 0.1; to convert angstroms into picometers, multiply by 100.

Bond type		Bond length, Å*		
Carbon–carbon				
<i>Single bond</i>				
Paraffinic: —C—C—		1.541(3)		
In presence of —C=C— or of aromatic ring		1.53(1)		
In presence of —C=O bond		1.516(5)		
In presence of two carbon–oxygen double bonds		1.49(1)		
In presence of two carbon–carbon double bonds		1.426(5)		
Aryl —C=O		1.47(2)		
In presence of one carbon–carbon triple bond: —C—C≡C—		1.460(3)		
In presence of one carbon–nitrogen triple bond: —C—C≡N		1.464(5)		
In compounds with tendency to dipole formation, e.g., C=C—C=O		1.44(1)		
In aromatic compounds		1.395(3)		
In presence of carbon–carbon double and triple bonds: —C=C—C≡C—		1.426(5)

TABLE 3.5 Bond Strengths

The quantity $D_0(\text{A—B})$ corresponds to the bond dissociation energy at 0K, all species considered to be ideal gases, for a bond A—B which is broken through the reaction: $\text{Eq. AB} \rightarrow \text{A} + \text{B}$

where

$$D_0 = \Delta H_f^\circ(\text{A}) + \Delta H_f^\circ(\text{B}) - \Delta H_f^\circ(\text{AB})$$

D_0 at 298 K, or ΔH_f° , is greater than D_0 at 0K by an amount which lies between RT and $3/2 RT$, or between 0.6 and 0.9 kcal · mol⁻¹. In polyatomic molecules this difference may be somewhat greater. It is important to note that the bond dissociation energy refers to the enthalpy change ΔH_f in the dissociation process.

The strengths of carbon–carbon bonds are greatest for triple bonds and typically decrease with bond order. Other factors play a role as well. A carbon–carbon single bond between two multiple bonds will share some additional electron density and be correspondingly strengthened. Bonds are weaker than “normal” when cleavage of a bond gives a particularly stable species. For example, cleavage of a single bond in ethylbenzene to give benzyl radical and methyl radical, $\text{C}_6\text{H}_5\text{CH}_2\text{—CH}_3 \rightarrow \text{C}_6\text{H}_5\text{CH}_2\bullet + \bullet\text{CH}_3$, is favorable because benzyl radical is stable. Thus, the C—C bond strength in this case is only 72 kcal/mol compared to the single bond of propane, which is 85 kcal/mol. Hexamethylethane may dissociate into two *t*-butyl radicals $[(\text{CH}_3)_3\text{C}\bullet]$. The combination of steric crowding and the formation of stabilized radicals makes the C—C bond strength in $(\text{CH}_3)_3\text{C—C}(\text{CH}_3)_3$ only about 68 kcal/mol. A few selected examples follow:

The numbers in parentheses following a numerical value represent the standard deviation of that value in terms of the final listed digit(s).

To convert the tabulated values (in kcal · mol⁻¹) to kJ · mol⁻¹, multiply by 4.184.

BOND AND GROUP DIPOLE MOMENTS

All bonds between equal atoms are given zero values. Because of their symmetry, methane and ethane molecules are nonpolar. The principle of bond moments thus requires that the CH_3 group moment equal one H—C moment. Hence the substitution of any aliphatic H by CH_3 does not alter the dipole moment, and all saturated hydrocarbons have zero moments as long as the tetrahedral angles are maintained.

The group moment always includes the C—X bond. When the group is attached to an aromatic system, the moment contains the contributions through resonance of those polar structures postulated as arising through charge shifts around the ring.

All values for bond and group dipole moments in Tables 3.6 and 3.7 were obtained in benzene solution.

TABLE 4.1 Solubility of Gases in Water

Explanation of the column headings

α , Volume of gas in milliliters (mL). The column or line entry headed “ α ” gives the volume of gas (in milliliters) at standard conditions (0°C and 760 mm or 101.325 kN·m⁻²) dissolved in 1 mL of water at the temperature stated (in degrees Celsius) and when the pressure of the gas without the water vapor is 760 mm.

A, Volume of gas in milliliters (mL). The line entry “A” indicates the same quantity as “ α ” except that the gas itself is at the uniform pressure of 760 mm when in equilibrium with water.

l, Volume of gas in milliliters (mL). The column headed “l” gives the volume of the gas (in milliliters) dissolved in 1 mL of water when the pressure of the gas plus that of the water vapor is 760 mm.

q, Weight of the gas in grams (g). The column headed “q” gives the weight of gas (in grams) dissolved in 100 g of water when the pressure of the gas plus that of the water vapor is 760 mm

TABLE 4.3 Vapor Pressure of Water for Temperatures from -10 to 120°C

The values in the table are for water in contact with its own vapor. Where the water is in contact with air at a temperature t in degrees Celsius, the following correction must be added: Correction (when $t \leq 40^{\circ}\text{C}$) = $p(0.775 - 0.000\,313\,t)/100$; correction (when $t > 50^{\circ}\text{C}$) = $p(0.0652 - 0.000\,087\,5\,t)/100$.

$t, ^{\circ}\text{C}$	p, mmHg	$t, ^{\circ}\text{C}$	p, mmHg	$t, ^{\circ}\text{C}$	p, mmHg	$t, ^{\circ}\text{C}$	p, mmHg

BOILING POINTS

TABLE 4.5A Boiling Points for Common Organic Solvents

Arranged in order of increasing boiling point

Compound name	bp (°C)	Other name	Compound name	bp (°C)	Other name
Ethylene oxide	10.6	Oxirane	Benzene	80.1	
Chloroethane	12.3	Ethyl chloride	Cyclohexane	80.7	
Furan	31.4		Propyl formate	80.9	
Methyl formate	31.5		Acetonitrile	81.6	
Diethyl ether	34.6	Ethyl ether	2-Propanol	82.4	Isopropyl alcohol
Propylene oxide	34.5		1,1-Dimethylethanol	82.4	<i>t</i> -Butanol
Pentane	36.1		Cyclohexene	83.0	
Bromoethane	38.4	Ethyl bromide	Diisopropyl amine	83.5	
Dichloromethane	39.8	Methylene chloride	1,2-Dichloroethane	83.7	
Dimethoxyethane	42.3	DME, glyme	Thiophene	84.2	
Carbon disulfide	46.3		Trichloroethylene	87.2	
1-Isopropoxy-2-propanol	47.9		Isopropyl acetate	88.2	
Ethyl formate	54.2		1-Bromo-2-methylpropane	91.5	Isobutyl bromide
Acetone	56.2	Dimethyl ketone	2,5-Dimethylfuran	93–94	
Methyl acetate	56.3		Ethyl chloroformate	94.0	
1,1-Dichloroethane	57.3		Allyl alcohol	96.6	
Dichloroethylene	60.6		1,2-Dichloropropane	96.8	
Chloroform	61.2		1-Propanol	97.2	<i>n</i> -Propyl alcohol
Methanol	64.7		Heptane	98.4	
Tetrahydrofuran	66.0	THF	1-Chloro-3-methylbutane	99.0	
Diisopropyl ether	68.0	Isopropyl ether	Ethyl propanoate	99.1	Ethyl propionate
Hexane	68.7		2-Butanol	99.6	<i>sec</i> -Butanol
1-Chloro-2-methylpropane	68.9	Isobutyl chloride	Formic acid	100.8	
1,1,1-Trichloroethane	74.0		Methylcyclohexane	100.9	
1,3-Dioxolane	74–75		1,4-Dioxane	101.2	
Carbon tetrachloride	76.7		Nitromethane	101.2	
Ethyl acetate	77.1		Propyl acetate	101.5	
1-Chlorobutane	77.9	Butyl chloride	2-Pentanone	101.7	Methyl propyl ketone
Ethanol	78.3		3-Pentanone	102.0	Diethyl ketone
2-Butanone	79.6	Methyl ethyl ketone	2-Methyl-2-butanol	102.0	<i>t</i> -Pentanol
2-Methyltetrahydrofuran	80.0		1,1-Diethoxyethane	102.7	

TABLE 4.5A Boiling Points for Common Organic Solvents (*continued*)*Arranged in order of increasing boiling point*

Compound name	bp (°C)	Other name	Compound name	bp (°C)	Other name
Butyl formate	106.6		4-Heptanone	143.7	Dipropyl ketone
2-Methyl-1-propanol	107.9	Isobutanol	<i>o</i> -Xylene	144.4	1,2-Dimethylbenzene
Toluene	110.6	Methylbenzene	2-Methoxyethyl acetate	144.5	
<i>sec</i> -Butyl acetate	112.3		1,1,2, 2-Tetrachloroethane	146.3	
1,1,2-Trichloroethane	113.5		3-Heptanone	147.8	Ethyl butyl ketone
Nitroethane	114.1		Tribromomethane	149.6	Bromoform
Pyridine	115.2		Nonane	150.8	
3-Pentanol	115.6		2-Heptanone	151	Methyl pentyl ketone
4-Methyl-2-pentanol	115.7	Methyl isobutyl ketone	Isopropylbenzene	152.4	Cumene
1-Chloro-2, 3-epoxypropane	116.1	Epichlorohydrin	<i>N,N</i> -Dimethylformamide	153.0	DMF
1-Butanol	117.7		Methoxybenzene	153.8	Anisole
Acetic acid	117.9		Ethyl lactate	154.5	
Isobutyl acetate	118.0		Cyclohexanone	155.7	
2-Pentanol	119.3	<i>sec</i> -Pentanol	Bromobenzene	156.2	
1-Bromo-3-methylbutane	119.7	Isopentyl bromide	1,2,3-Trichloropropane	156.9	
1-Methoxy-2-propanol	120.1		1-Hexanol	157.5	
2-Nitropropane	120.3	Nitroisopropane	Propylbenzene	159.2	
Tetrachloroethylene	121.1		Cyclohexanol	161.1	
Ethyl butanoate	121.6	Ethyl butyrate	Bis(2-methoxyethyl) ether	160	Diglyme
3-Hexanone	123	Ethyl propyl ketone	Isopentyl propanoate	160.2	Isopentyl propionate
2,4-Dimethyl-3-pentanone	124	Diisopropyl ketone	2-Heptanol	160.4	
2-Methoxyethanol	124.6		Pentachloroethane	160.5	
Octane	125.7		2-Furaldehyde	161.8	Furfural
Butyl acetate	126.1		2,6-Dimethyl-4-heptanone	168.1	Diisobutyl ketone
Diethyl carbonate	126.8		4-Hydroxy-4-methyl-2-pentanone	169.2	
2-Hexanone	127.2	Methyl butyl ketone	2-Furanmethanol	170.0	2-Hydroxy methylfuran
1-Chloro-2-propanol	127.4		Ethoxybenzene	170	Phenetole
2-Chloroethanol	128.6		2-Butoxyethanol	170.2	Butyl cellosolve
1-Nitropropane	131.2		Diisopentyl ether	173.4	
Chlorobenzene	131.7		Decane	174.2	
1,2-Dibromoethane	131.7		1,3-Dichloro-2-propanol	174.3	
4-Methyl-2-pentanol	131.7		Cyclohexyl acetate	174–175	
3-Methyl-1-butanol	132.0		1-Heptanol	175.8	
Cyclohexylamine	134.8	Aminocyclohexane	Furfuryl acetate	175–177	
2-Ethoxyethanol	134.8		4-Isopropyl-1-methylbenzene	177.1	<i>p</i> -Cymene
Ethylbenzene	136.2				
1-Pentanol	138				
<i>p</i> -Xylene	138.4	1,4-Dimethylbenzene			
<i>m</i> -Xylene	139.1	1,3-Dimethylbenzene			
Acetic anhydride	140.0				
2,4-Pentanedione	140.6	Acetylacetone			
Isopentyl acetate	142				
Dibutyl ether	142.4				

TABLE 4.5A Boiling Points for Common Organic Solvents (*continued*)*Arranged in order of increasing boiling point*

Compound name	bp (°C)	Other name	Compound name	bp (°C)	Other name
Isopentyl butanoate	178.6	Isopentyl butyrate	<i>o</i> -Chloroaniline	208.8	1-Amino-2-chlorobenzene
Bis(2-chloroethyl) ether	178.8	Dichloro diethyl ether	Nitrobenzene	210.8	
2-Octanol	179		Ethyl benzoate	212.4	
1,2-Dichlorobenzene	180.4	<i>o</i> -Dichlorobenzene	Isophorone	215.2	3,5, 5-Trimethylcyclohex-2-en-1-one
Ethyl acetoacetate	180.8				
Phenol	181.8	Hydroxybenzene	Naphthalene	217.7	
2-Ethyl-1-hexanol	184.3		2-(2-Ethoxyethoxy) ethyl acetate	218.5	
Aniline	184.4	Aminobenzene	Acetamide	221.2	
Benzyl ethyl ether	185.0		Methyl salicylate	223.0	
Diethyl oxalate	185.4		Diethyl maleate	225.3	
1,2-Propanediol	188	Propylene glycol	1,4-Butanediol	230	
Bis(2-ethoxyethyl) ether	188.4		Propyl benzoate	231.2	
Dimethylsulfoxide	189.0	DMSO	1-Decanol	230.2	
1,2-Ethanediol	190.2	Diacetoxyethane diacetate	Phenylacetonitrile	233.5	Cyano-methylbenzene
Benzonitrile	191.0	Cyanobenzene	Quinoline	237	
2,5-Hexanedione	191.4		Tributyl borate	238.5	
2-(2-Methoxyethoxy) ethanol	194.1		Propylene carbonate	240	
<i>N,N</i> -Dimethylaniline	194.2	Dimethyl-aminobenzene	2-Phenoxyethanol	240	
1-Octanol	195.2		Bis(2-hydroxyethyl) ether	245	Diethylene glycol
1,2-Ethanediol	197.3	Ethylene glycol	Dibutyl oxalate	245.5	
Diethyl malonate	199.3		Butyl benzoate	250	
Methyl benzoate	199.5		1,2,3-Propanetriol triacetate	258–259	Glycerol triacetate
<i>o</i> -Toluidine	200.4	1-Amino-2-methylbenzene	1-Chloronaphthalene	259.3	
<i>p</i> -Toluidine	200.6	1-Amino-4-methylbenzene	Isopentyl benzoate	262	
2-(2-Ethoxyethoxy) ethanol	202		<i>trans</i> -Ethyl cinnamate	271.0	
Acetophenone	202.1	Methyl phenyl-ketone	Bis (2-(2-methoxy-ethoxy)-ethyl) ether	275.3	Triglyme
1,2-Dibutoxyethane	203.6		1-Methoxy-2-nitrobenzene	277	
1,2-Phenylethanol	203.9	Phenethyl alcohol	Isopentyl salicylate	277–278	
<i>m</i> -Toluidine	203.4	1-Amino-3-methylbenzene	1-Bromonaphthalene	281.1	
Benzyl alcohol	205.5	Hydroxy-methylbenzene	Dimethyl <i>o</i> -phthalate	283.7	1,2-Bis(carbo-methoxy) benzene
Camphor	207	1,7,7-Trimethyl-bicyclo[2.2.1]heptan-2-one	2,2'-(Ethylenedioxy) bisethanol	285	
1,3-Butanediol	207.5		Glycerol	290	
1,2,3,4-Tetrahydronaphthalene	207.6	Tetralin	Diethyl <i>o</i> -phthalate	295	
γ -Valerolactone	207–208		Benzyl benzoate	323.5	
			Dibutyl <i>o</i> -phthalate	340.0	
			Dibutyl decanedioate	344–345	

TABLE 4.5B Boiling Points for Common Organic Solvents

Arranged alphabetically by solvent name

Compound name	bp (°C)	Other name	Compound name	bp (°C)	Other name
Acetamide	221.2		Chlorobenzene	131.7	
Acetic acid	117.9		1-Chlorobutane	77.9	Butyl chloride
Acetic anhydride	140.0		1-Chloro-2,3-epoxypropane	116.1	Epichlorohydrin
Acetone	56.2	Dimethyl ketone	1-Chloro-2-propanol	127.4	
Acetonitrile	81.6		Chloroethane	12.3	Ethyl chloride
Acetophenone	202.1	Methyl phenyl ketone	2-Chloroethanol	128.6	
Allyl alcohol	96.6		Chloroform	61.2	
Aniline	184.4	Aminobenzene	1-Chloro-3-methylbutane	99.0	
Benzene	80.1		1-Chloro-2-methylpropane	68.9	Isobutyl chloride
Benzonitrile	191.0	Cyanobenzene	1-Chloronaphthalene	259.3	
Benzyl alcohol	205.5	Hydroxy-methylbenzene	Cyclohexane	80.7	
Benzyl benzoate	323.5		Cyclohexanol	161.1	
Benzyl ethyl ether	185.0		Cyclohexanone	155.7	
Bis(2-(2-methoxyethoxy)-ethyl) ether	275.3	Triglyme	Cyclohexene	83.0	
Bis(2-chloroethyl) ether	178.8	Dichloro diethyl ether	Cyclohexyl acetate	174–175	
Bis(2-ethoxyethyl) ether	188.4		Cyclohexylamine	134.8	Aminocyclohexane
Bis(2-hydroxyethyl) ether	245	Diethylene glycol	Decane	174.2	
Bis(2-methoxyethyl) ether	160	Diglyme	1-Decanol	230.2	
Bromobenzene	156.2		1,2-Dibromoethane	131.7	
Bromoethane	38.4	Ethyl bromide	1,2-Dibutoxyethane	203.6	
1-Bromo-2-methylpropane	91.5	Isobutyl bromide	Dibutyl decanedioate	344–345	
1-Bromo-3-methylbutane	119.7	Isopentyl bromide	Dibutyl ether	142.4	
1-Bromonaphthalene	281.1		Dibutyl <i>o</i> -phthalate	340.0	
1,3-Butanediol	207.5		Dibutyl oxalate	245.5	
1,4-Butanediol	230		1,2-Dichlorobenzene	180.4	<i>o</i> -Dichlorobenzene
1-Butanol	117.7		Dichloroethylene	60.6	
2-Butanol	99.6	<i>sec</i> -Butanol	Dichloromethane	39.8	Methylene chloride
2-Butanone	79.6	Methyl ethyl ketone	1,1-Dichloroethane	57.3	
2-Butoxyethanol	170.2	Butyl cellosolve	1,2-Dichloroethane	83.7	
Butyl acetate	126.1		1,2-Dichloropropane	96.8	
<i>sec</i> -Butyl acetate	112.3		1,3-Dichloro-2-propanol	174.3	
Butyl benzoate	250		1,1-Diethoxyethane	102.7	
Butyl formate	106.6		Diethyl carbonate	126.8	
Camphor	207	1,7,7-Trimethylbicyclo [2.2.1] heptan-2-one	Diethyl ether	34.6	Ethyl ether
			Diethyl maleate	225.3

TABLE 4.6 Molecular Elevation of the Boiling Point*Ebullioscopic constants*

Molecular weights can be determined with the relation

$$M = K_b \frac{1000 w_2}{w_1 \Delta T_b}$$

where ΔT_b is the elevation of the boiling point brought about by the addition of w_2 grams of solute to w_1 grams of solvent and K_b is the ebullioscopic constant. In the column headed "Barometric correction" is given the number of degrees for each millimeter of difference between the barometric reading and 760 mmHg to be subtracted from K_b if the pressure is lower, or added if higher, than 760 mm. In general, the effect is within experimental error if the pressure is within 10 mm of 760 mm.

Distillation is an important historical method for the separation of liquids. A mixture or solution of two liquids is heated until the vapor pressure of the lower boiling compound reaches the pressure of the surroundings. This may be ambient pressure or a lowered pressure caused by application of a vacuum. In either event, vaporization occurs, the vapors are condensed on a cold surface, and the condensed liquid is collected. If the boiling points of the two liquids are sufficiently different given the pressure and efficiency of the apparatus, separation may be achieved. A zeotrope is a mixture that can be separated by distillation.

In contrast, certain mixtures of two (binary) or three (ternary) components form constant boiling mixtures that cannot be separated by distillation. In such cases, each component contributes a fixed amount and the boiling point of the mixture is characteristic of the components. Such a system is called an azeotrope. The boiling point of an azeotrope may be higher or lower than that of the individual components. Common binary azeotropes are listed in Table 4.7 and ternary azeotropes are listed in Table 4.8.

TABLE 4.7 Binary Azeotropic (Constant Boiling) Mixtures

A zeotrope is a mixture that can be separated by distillation.

A. Binary azeotropes containing water

System	BP of azeotrope, °C	Composition, wt %	
		Water	Other component
Inorganic acids

FREEZING POINTS

Crystalline organic compounds typically have a characteristic melting point. In some cases, a compound may have more than one arrangement in the crystal and such polymorphs will exhibit differences in melting behavior. For the most part, however, the melting point of a compound is characteristic and invariant for a pure sample. When contaminated by a second substance, however, the melting (or freezing) point is typically lowered.

A classical test used to determine if two samples that have the same melting point are identical is to intimately mix them and record the melting point of the mixture. If the melting point of the blend is identical to that of each individual compound prior to mixing, the two substances are judged to be identical. When the two compounds are not the same, the melting point of the mixture is typically lowered and broadened.

The melting or freezing point depression can be used to determine an approximate molecular weight for a given substance. The cryoscopic constant K_f gives the depression of the melting point ΔT (in degrees Celsius) produced when 1 mol of solute is dissolved in 1000 g of a solvent. It is applicable only to dilute solutions for which the number of moles of solute is negligible in comparison with the number of moles of solvent. Because camphor is conveniently available and has a large K_f value, it is often used in this application. A known amount of the substance whose molecular weight is to be determined (the solute) is mixed with a larger amount of camphor (the solvent). Melting the mixture permits intimate mixing. The lowering or depression of the freezing point is then used to calculate the molecular weight from the following equation

$$M_2 = \frac{1000w_2K_f}{w_1\Delta T}$$

where M_2 is the molecular weight to be determined of the solute, w_1 is the exact weight of the solvent, w_2 is the exact weight of the added compound of unknown molecular mass, ΔT is the change in temperature, and K_f is the cryoscopic constant given in the Table 4.9A.

In Table 4.9A, a range of compounds and their cryoscopic constants are recorded. All of the same data are included in Table 4.9B but they are rearranged in order of increasing melting point at the left and decreasing K_f at the right.

VISCOSITY, DIELECTRIC CONSTANT, DIPOLE MOMENT, SURFACE TENSION, AND REFRACTIVE INDEX

Several additional physical properties are summarized in Table 4.10. These are viscosity, dielectric constant, dipole moment, and surface tension for selected common organic compounds.

Viscosity

Viscosity may be thought of as a fluid's resistance to flow or internal friction. It is characterized by the property called viscosity, which is designated η (eta). A fluid passing through a tube will flow more freely if its viscosity is low and more slowly if it is more viscous. Viscosity is given in Table 4.10 in units of milliNewton-second-meter⁻² or mN·s·m⁻². In fluid mechanics, the unit "poise" is equal to a force of 1 dyne·cm⁻² for two fluids passing each other at a rate of 1 cm·s⁻¹. Viscosity is typically greater at lower temperatures; temperatures (in °C) are given in parentheses in the table.

Dielectric Constant

The dielectric constant (or relative permittivity) is usually expressed using the symbol ϵ . The dielectric ϵ is defined as the ratio of electric fields E_0/E for a vacuum and a substance placed between the plates of a capacitor. The dielectric constant of a vacuum is 1 and substances that can orient to greater or lesser extents in the applied field will have higher dielectric constants. The dielectric constant of heptane at 20°C is ~1.9. Acetonitrile, CH₃C≡N:, has a dielectric constant at 20°C of 37.5. The dielectric constant for water is near 80.

The choice of a solvent for a particular reaction will usually depend on more than one variable. These include the liquid temperature range, the dielectric constant, and whether or not the solvent is reactive in the chemical reaction. The most important consideration in the latter context is often the presence of an easily transferred proton. Certain solvents, such as acetone, are considered aprotic but may transfer a proton under basic conditions. Thus the designations given below are general and approximate. They are intended to guide the reader to the more detailed information contained in the full tables.

Common Solvents Listed in Order of Increasing Dielectric Constant (Ascending Polarity)

Aprotic Solvents		Protic Solvents
Dielectric constants < 15	Dielectric constants > 15	Dielectric range 6–80
carbon disulfide	acetone	acetic acid
carbon tetrachloride	benzonitrile	trifluoroacetic acid
tetrachloroethylene	hexamethylphosphoramide	phenols
1,2-dichloroethylene	<i>N</i> -methylpyrrolidone	butanols
chlorobenzene	nitrobenzene	propanols
dichloromethane	nitromethane	ethanol
chloroform	<i>N,N</i> -dimethylformamide (DMF)	2,2,2-trifluoroethanol
1,4-dioxane	acetonitrile	methanol
diphenyl ether	dimethyl sulfoxide (DMSO)	various glycols
diethyl ether		water

Aprotic Solvents		Protic Solvents
Dielectric constants < 15	Dielectric constants > 15	Dielectric range 6–80
tetrahydrofuran (THF) 1,2-dimethoxyethane (DME) ethyl acetate butyl acetate <i>N,N</i> -dimethylaniline pyridine		

Dipole Moment

The dipole moment of a molecule is the vectorial sum of the individual dipoles within it. Bond dipoles are usually represented using the symbol μ and are expressed in units of Debye. The dipoles result from charge separation. The carbon–carbon bond in ethane, $\text{H}_3\text{C}-\text{CH}_3$ is symmetrical and not expected to have a dipole moment. The carbon–oxygen bond of methanol (CH_3OH), on the other hand, links two elements of differing electronegativity and is expected to have a significant molecular dipole. Methanol's molecular dipole is ~ 1.7 whereas, for ethane, it is 0.

Experimentally, the molecular dipole can be measured. Individual bond dipoles cannot be measured but they have been inferred from experimental data for a variety of compounds. Estimates of the molecular dipole can be made by vector addition of individual moments. Such estimates (calculations) are indicative but may differ significantly from the measured values. The latter are recorded in Table 4.10.

Four examples of dipole moments are instructive. First, the dipoles for chloromethane and dichloromethane are 1.87 D and 1.60 D, respectively. Although two chlorine–carbon bonds are present in the latter, the dipole is not along either but rather bisects the angle between them. This is illustrated schematically using the stylized arrow with its positive end in the form of a cross. The orientation question is shown clearly in the rigid dichlorobenzene framework. The dipole is 2.13 D for the *ortho*-isomer and 0 D when the dipoles exactly oppose each other.

The orientation of dipoles can be assessed by comparing otherwise identical molecules. For example, amino is electron releasing and nitro is electron withdrawing. The molecular dipoles (1.53 D for aniline and 4.22 D for nitrobenzene) add to give an overall molecular dipole of 6.3 D for 4-nitroaniline. The importance of two polar C–O bonds should be large

if they are added and small if they oppose. The dynamics of the system must be taken into account for structures such as 1,2-dihydroxyethane (ethylene glycol), which is illustrated in the eclipsed and staggered conformers.

Surface Tension

The surface tension is the force that acts on the surface of a liquid that tends to minimize the surface area of the liquid. Surface tension is also sometimes referred to as interfacial force or interfacial tension. The property of surface tension is temperature dependent. For the majority of compounds the dependence of the surface tension γ on the temperature can be given as

$$\gamma = a - bt$$

where a and b are constants and t is the temperature in $^{\circ}\text{C}$.

TABLE 4.10 Viscosity, Dielectric Constant, Dipole Moment, and Surface Tension of Selected Organic Substances

States:	[g], gas	Solvents:	[B], benzene,	C_6H_6
	[lq], liquid		[C], carbon tetrachloride,	CCl_4
			[D], 1,4-dioxane,	$\text{C}_4\text{H}_8\text{O}_2$
			[H], hexane,	C_6H_{14}
			[cH], cyclohexane,	C_6H_{12}

The temperature in degrees Celsius at which the viscosity, dielectric constant, dipole moment, and surface tension of a substance were measured is shown in this table in parentheses after the value. The solvent used or the physical state of the substance are also shown in parentheses after the temperature in square brackets, for example, [g] or [b]

Alternate names for entries are listed in Table 1-14 at the bottom of each double page.

Substance	Viscosity η , $\text{mN} \cdot \text{s} \cdot \text{m}^{-2}$	Dielectric constant ϵ	Dipole moment, D	Surface tension, $\text{dyn} \cdot \text{cm}^{-1}$

Table 5.4 Group Contributions for the Estimation of Critical Properties	5.88

ENTHALPIES AND GIBBS (FREE) ENERGIES OF FORMATION, ENTROPIES, AND HEAT CAPACITIES

The tables in this section contain values of the enthalpy (ΔH_f) and Gibbs (ΔG_f , free) energy of formation, entropy (S), and heat capacity (C_p) at 298.15 K (25°C). The tables cover common organic compounds. No values are given in these tables for metal alloys or other solid solutions, for fused salts, or for substances of undefined chemical composition.

For a more complete listing of compounds see the tables in *Selected Values of Chemical Thermodynamical Properties*, by D. D. Wagman *et al.*, National Bureau of Standards Technical Notes 270-3, 270-4, 270-5, 270-6, 270-7, and 270-8, Washington; *JANAF Thermochemical Tables*, by D. R. Stull and H. Prophet, National Bureau of Standards Publication 37, Washington; supplements to JANAF appearing in *J. Phys. Chem. Ref. Data*; D. R. Stull, E. F. Westrum, Jr., and G. C. Sinke, *The Chemical Thermodynamics of Organic Compounds*, Wiley-Interscience, New York, 1969; and I. Barin and O. Knacke, *Thermochemical Properties of Inorganic Substances*, Springer-Verlag, Berlin, 1973.

The values of the thermodynamic properties of the pure substances given in these tables are, for the substances in their standard states, defined as follows:

Pure solid (c) or liquid (liq). The substance is in the condensed phase under a pressure of 1 atm.

Gas (g). The standard state is the hypothetical ideal gas at unit fugacity, in which state the enthalpy is that of the real gas at the same temperature and at zero pressure.

The values of ΔH_f° and ΔG_f° given in the tables represent the change in the appropriate thermodynamic quantity when one gram formula weight of the substance in its standard state is formed, isothermally at the indicated temperature, from the elements, each in its appropriate standard reference state. The standard reference state at 25°C for each element has been chosen to be the standard state that is thermodynamically stable at 25°C and 1 atm pressure. The standard reference states are indicated in the tables by the fact that the values of ΔH_f° and ΔG_f° are exactly zero.

The values of S° represent the virtual or "thermal" entropy of the substance in the standard state at 298.15 K, omitting contributions from nuclear spins. Isotope mixing effects are also excluded except in the case of the ^1H – ^2H system.

The physical state of each substance is indicated in the column headed "State" as crystalline solid (c), liquid (liq), gaseous (g), or amorphous (amorp). Solutions in water are listed as aqueous (aq). Solutions in water are designated as aqueous, and the concentration of the solution is expressed in terms of the number of moles of solvent associated with 1 mol of the solute. If no concentration is indicated, the solution is assumed to be dilute. The standard state for a solute in aqueous solution is taken as the hypothetical ideal solution of unit molality (indicated as std state, $m = 1$). In this state the partial molal enthalpy and the heat capacity of the solute are the same as in the infinitely dilute real solution (aq. m).

CRITICAL PHENOMENA

The *critical temperature* T_c of a gas is the temperature above which the gas cannot be liquefied no matter how high the pressure.

The *critical pressure* P_c is the lowest pressure which will liquefy the gas at its critical temperature.

The *critical molar volume* V_c is the volume of 1 mol at the critical temperature and the critical pressure. It can be computed from the critical density ρ_c as follows:

$$\frac{\text{Molecular weight in g} \cdot \text{mol}^{-1}}{\rho_c \text{ in g} \cdot \text{cm}^{-3}} = V_c \text{ in cm}^3 \cdot \text{mol}^{-1}$$

The critical pressure, critical molar volume, and critical temperature are the values of the pressure, molar volume, and thermodynamic temperature at which the densities of coexisting liquid and gaseous phases just become identical. At this critical point the *critical compressibility factor* Z_c is

$$Z_c = \frac{P_c V_c}{RT_c}$$

Since pressure, volume, and temperature are related to the corresponding critical properties, the function connecting the reduced properties becomes the same for each substance. The reduced property is expressed as a fraction of the critical property.

$$P_r = \frac{P}{P_c} \quad V_r = \frac{V}{V_c} \quad T_r = \frac{T}{T_c}$$

Estimation of Critical Properties

When the critical properties are unavailable, they may be estimated employing structural contributions to estimate T_c , P_c , and V_c . Lydersen's critical-property increments* provide good estimates for T_c and P_c ; Vetere's group contributions† yield reasonable estimates for V_c . The units employed are kelvins, atmospheres, and cubic centimeters per mole. Typical errors in estimated values are less than 2% for T_c but may rise up to 5% for higher-molecular-weight (greater than 100) nonpolar materials; errors are uncertain for molecules with multifunctional polar groups. Errors for estimated values of P_c and V_c are about double those for T_c .

The relations are

$$T_c = T_b \left[0.567 + \sum \Delta_T - \left(\sum \Delta_T \right)^2 \right]^{-1}$$
$$P_c = M \left(0.34 + \sum \Delta \right)^{-2}$$
$$V_c = 33 + \left[\sum_i \left(M_i \Delta_v \right) \right]^{1.029}$$

where T_b is the normal boiling point and M is the molular weight. Group contributions are listed in Table 5.4.

TABLE 5.4 Group Contributions for the Estimation of Critical Properties

There are no increments for hydrogen. All bonds shown as free are connected with atoms other than hydrogen. Values in parentheses are based upon very few experimental values.

X-RAY DIFFRACTION		6.121

For more than half a century, spectroscopy has been the key structural tool for organic chemistry and biochemistry. This remains the case today although the availability of enhanced methods of X-ray analysis has somewhat altered the balance in both disciplines. A vast array of specialized texts are available that survey spectroscopic techniques in general or individual methods in particular. It would be folly to try to duplicate those efforts here. A brief overview of the methods may prove helpful and serve as a reminder for the practitioner who consults this handbook.

ULTRAVIOLET-VISIBLE SPECTROSCOPY

Generally, spectroscopic methods involve the absorption of radiation at certain wavelengths (and therefore certain energies) by molecules. For the techniques of ultraviolet-visible (UV-VIS) and infrared spectroscopy, there is an inverse proportionality between the amount of energy absorbed and the structural information that is revealed. The UV-VIS wavelength range is generally considered to be 200–800 nm. At the lower end, oxygen absorbs energy and the lowest end of the range is called the “vacuum UV.” Relatively limited structural information may be obtained from the typically broad bands that are observed. Even so, the electronic transitions that are observed are sensitive to structure. Individual absorbing groups or chromophores absorb light at a characteristic wavelength. The absorption usually shifts when two or more chromophores are linked or in conjugation.

The UV-VIS technique may be used quantitatively by application of Beer’s law:

$$\varepsilon = abc.$$

In this relationship, ε is the extinction coefficient that is characteristic of a given compound. The values a and c represent absorption and concentration, respectively. The

UV Spectrum of Naphthalene.

variable b is the pathlength of light through the sample, usually 1 cm. If the extinction coefficient is known, the measured absorption will give the compound's concentration.

The spectrum of naphthalene is shown above. Its broad bands reflect the absorption of energy by the extended pi-electron system.

The tables in this section present the essential data required for interpretation of UV-VIS spectra. Table 6.1 lists representative chromophores. These are identified by λ_{\max} , the maximum height of any given peak, and by ϵ_{\max} , the extinction coefficient at the maximum wavelength. Both the wavelength and absorption intensity are characteristic of individual chromophores.

Table 6.2 lists the ultraviolet cutoff for a variety of solvents commonly used in UV-VIS spectroscopy. The solvent chosen must dissolve the sample, yet be relatively transparent in the spectral region of interest. Typically, very low concentrations of sample will be present in the solvent. It is therefore important to avoid solvents that have even weak absorptions near the solute's bands of interest. Methanol and ethanol are two of the most commonly used solvents. Care must be exercised when using the latter that no benzene (an azeotropic drying agent) is present as this will alter the solvent's transparency. Normally, this will not be a problem in spectral grade solvents.

Tables 6.3–6.5 record data developed to undertake structural analysis in systems possessing chromophores that are conjugated or otherwise interact with each other. Chromophores within a molecule interact when linked directly to each other or when they are forced into proximity owing to structural constraints. Certain combinations of functional groups comprise chromophoric systems that exhibit characteristic absorption bands. In the era when UV-VIS was one of the principal spectral methods available to the organic chemist, sets of empirical rules were developed to extract as much information as possible from the spectra. The correlations referred to as Woodward's rules or the Woodward-Fieser rules, enable the absorption maxima of dienes (Table 6.3) and enones and dienones (Table 6.4) to be predicted. When this method is applied, wavelength increments correlated to structural features are added to the respective base values (absorption wavelength of parent compound). The data refer to spectra determined in methanol or ethanol. When other solvents are used, a numerical correction must be applied. These corrections are recorded in Table 6.5.

The benzene ring is a common structural element in organic chemistry. It is rigid and substituents are arranged in a fixed orientation. Shifts in the wavelength are expected for substituents that can interact electronically with the aromatic ring. Typically, shifts to longer wavelength (and intensification of the absorption band) are observed for any ring substitution. In the absence of conjugation, the shifts are small. Also, interposition of a single methylene group, or *meta* orientation within the aromatic ring, is sufficient to insulate chromophores almost completely from each other. With electron-withdrawing substituents, practically no change in the maximum position is observed. Directly conjugated groups may produce quite large spectral shifts. Examples include double and triple bonds and carbonyl groups. The spectra of heteroaromatics are related to their isocyclic analogs, but only in a general way. As with benzene, the magnitude of substituent shifts can be estimated, but tautomeric possibilities may invalidate the empirical method. Table 6.6 records data for substituents bonded directly to a benzene ring.

When electronically complementary groups are situated *para* to each other in disubstituted benzenes, there is a more pronounced shift to a longer wavelength than would be expected from the additive effect due to the extension of the chromophore from the electron-donating group through the ring to the electron-withdrawing group. When the *para* groups are not complementary, or when the groups are situated *ortho* or *meta* to each other, disubstituted benzenes show a more or less additive effect of the two substituents on the wavelength maximum. Calculation of the principal band of selected substituted benzenes is illustrated in Table 6.7.

TABLE 6.3 Absorption Wavelength of Dienes

Heteroannular and acyclic dienes usually display molar absorptivities in the 8000–20000 range, whereas homoannular dienes are in the 5000–8000 range.

Poor correlations are obtained for cross-conjugated polyene systems such as

The correlations presented here are sometimes referred to as Woodward's rules or the Woodward-Fieser rules.

PHOTOLUMINESCENCE

Luminescence processes may be categorized by the excitation method used with any particular luminescent molecule. Photoluminescence is the excitation process that involves the interaction of electromagnetic radiation with photons. The process is termed chemiluminescence when the exciting energy results from a chemical reaction. Any luminescence arising from an organism is referred to as bioluminescence.

The most common application of photoluminescence is found in fluorescence spectroscopy. Fluorescence is the immediate release of electromagnetic energy from an excited molecule or release of the energy from the singlet state. If the emitted energy arises from the triplet state or is delayed, the process is referred to as phosphorescence.

A fluorescence spectrum is characteristic of a given compound. It is observed as a result of radiative emission of the energy absorbed by the molecule. The observed spectrum does not depend on the wavelength of the exciting light, except that the spectrum will be more intense if irradiation occurs at the absorption maximum. The spectral intensity is called the quantum efficiency and is usually abbreviated as Φ . The quantum yield or quantum efficiency, Φ , which is solvent dependent, is the ratio: Φ = number of quanta emitted/number of quanta absorbed. Approximate values of quantum efficiencies are as follows: naphthalene, ~0.1; anthracene, ~0.3; indole, ~0.5; and fluorescein, ~0.9.

An equation similar to Beer’s law applies to fluorescence spectroscopy at dilute concentrations. In its most general form, it is given as

$$F = \Phi I_0(1 - e^{-\epsilon bc}).$$

In this equation, F is the observed fluorescence, Φ is the quantum efficiency (see above), I_0 is the intensity of the incident radiation, ϵ is the molar absorptivity, b is the cell’s path length, and c is the compound’s molar concentration.

The appearance of a fluorescence spectrum is reminiscent of a UV–VIS spectrum. The fluorescence spectrum for a 3-substituted indole derivative is shown in Figure 6.1. The

FIGURE 6.1 Fluorescence Spectrum for a 3-substituted indole derivative.

compound concentration was approximately 10^{-5} M in acetonitrile (CH_3CN). The sample was irradiated at a wavelength of 283 nm. The abscissa shows the wavelength in nanometers (nm) and the intensity ("int") is recorded on the ordinate. The maximum emission intensity is observed at 356 nm. The longest wavelength peak (λ_{max}) is observed at approximately 680 nm.

INFRARED SPECTROSCOPY

Infrared (IR) and Raman spectroscopy rely on the interaction of a bond between two elements and IR radiation in the $400\text{--}4000\text{cm}^{-1}$ range. The two techniques are distinct but closely related. Historically, infrared analysis has been the more widely used in organic chemistry but much of the brief discussion that follows applies equally to both methods.

A chemical bond may be considered as a spring to which two weights are attached. The weights are atoms of different atomic masses. The length and strength of the spring may be correlated to the length and strength of the chemical bond. Each bond will vibrate at a frequency that is characteristic of the attached atoms and the type of bond (*i.e.*, single, double, or triple) between them. Radiation of an appropriate frequency will be absorbed by the bond and the wavelength at which this occurs will be detected and recorded by the instrument in the spectrum. Indeed, most molecules have many bonds so multiple peaks are observed in an IR spectrum.

An electrical dipole is required for IR energy to be efficiently absorbed by a molecule. Thus, bonds between different elements will give more prominent absorption peaks than will symmetrical bonds. This is because the bond's dipole moment changes as the bond stretches and contracts. Symmetrical bonds do not change dipole moment even if the bond distance changes. Usually, the most prominent peaks are observed when the electronegativity difference between the bound elements is greatest. Thus, a C—O bond will usually be more prominent than a C—H bond.

The position (frequency) of the absorption depends on the strength of the bond linking them. Thus, single, double, and triple bonds are observed in characteristic ranges. In addition, the frequency is related to the masses of the attached atoms. The largest mass differences occur when an element is attached to hydrogen. Such bonds as C—H, O—H, and N—H typically are observed in the $2900\text{--}3600\text{cm}^{-1}$ range.

The remarkable versatility of NMR as an analytical method has diminished the importance of IR analysis in modern laboratories but it remains a very useful technique. The very small amount of sample required and the prominence of functional group absorption means that the progress of a reaction can be monitored very conveniently. For example, the reduction of an aldehyde to an alcohol will be accompanied by the disappearance of the prominent C=O peak and the appearance of a C—OH absorption. Because both peaks are so readily identifiable in a small sample, the reaction is easy to follow and its completeness can be assayed.

TABLE 6.11 Absorption Frequencies of Single Bonds to Hydrogen

<i>Abbreviations Used in the Table</i>		
	m, moderately strong	var, of variable strength
	m-s, moderate to strong	w, weak
	s, strong	w-m, weak to moderately strong
Group	Band, cm^{-1}	Remarks

Hydroxyl group O—H compounds		
Primary aliphatic alcohols	3 640–3 630 (s) 1 350–1 260 (s) 1 085–1 030 (s)	Only in very dilute solutions in nonpolar solvents OH bending Also broad band at $700\text{--}600\text{ cm}^{-1}$
Secondary aliphatic alcohols	3 625–3 620 (s) 1 350–1 260 (s) 1 125–1 085 (s)	See comments under primary aliphatic alcohols Also for α -unsaturated and cyclic tertiary aliphatic alcohols
Tertiary aliphatic alcohols	3 620–3 610 (s) 1 410–1 310 (s) 1 205–1 125 (s)	See comments under primary aliphatic alcohols
Aryl—OH	ca 3 610 (s) 1 410–1 310 (s) 1 260–1 180 (s) 1 085–1 030 (s)	See comments under primary aliphatic alcohols Also for unsaturated secondary aliphatic alcohols
Carboxylic acids	3 300–2 500 (w–m) 995–915 (s)	Broad Broad diffuse band
Enol form of β -diketones	2 700–2 500 (var)	Broad

TABLE 6.11 Absorption Frequencies of Single Bonds to Hydrogen (*continued*)

Group	Band, cm^{-1}	Remarks
Hydroxyl group O—H compounds (<i>continued</i>)		
Free oximes	3 600–3 570(w–m)	Shoulder
Free hydroperoxides	3 560–3 530 (m)	
Peroxy acids	ca 3 280 (m)	
Phosphorus acids	2 700–2 560 (m)	Broad
Water in solution	3 710	When solution is damp
Intermolecular H bond Dimeric	3 600–3 500	Rather sharp. Absorptions arising from H bond with polar solvents also appear in this region. Broad
Polymeric	3 400–3 200 (s)	
Intramolecular H bond Polyvalent alcohols Chelation	3 600–3 500 (s) 3 200–2 500	Sharper than dimeric band above Broad and occasionally weak; the lower the frequency, the stronger the intramolecular bond
Water of crystallation (solid state spectra)	3 600–3 100 (w)	Usually a weak band at 1 640–1 615 cm^{-1} also. Water in trace amounts in KBr disks shows a broad band at 3 450 cm^{-1} .
Amine, imine, ammonium, and amide N—H		
Primary amines Aliphatic	3 550–3 300 (m) 1 650–1 560 (m) 1 090–1 020 (w–m) 850–810 (w–m)	Two bands in this range With α -carbon branching at 795 cm^{-1} and strong
Aromatic	495–445 (m–s) ca 290 (s)	Broad Broad
	1 350–1 260 (s) 445–345	Also for secondary aryl amines
Amino acids	3 100–3 030 (m)	Values for solid states; broad bands also (but not always) near 2 500 and 200 cm^{-1}
Amino salts	2 800–2 400 (m) 1 625–1 560 (m) 1 550–1 550 (m)	Number of sharp bands; dilute solution
	3 550–3 100 (m)	Values for solid state
	ca 3 380	Dilute solutions
	ca 3 280	

TABLE 6.11 Absorption Frequencies of Single Bonds to Hydrogen (*continued*)

Group	Band, cm^{-1}	Remarks
Amine, imine, ammonium, and amide N—H (<i>continued</i>)		
Secondary amines	3 550–3 400 (w) 1 580–1 490 (w) 1 190–1 170 (m) 1 145–1 130 (m) 455–405 (w–m)	Only one band, whereas primary amines show two bands Often too weak to be noticed
Salts	ca 2 500 ca 2 400 1 620–1 560 (m–s)	Sharp; broad values for solid state Sharp; broad values for solid state
Tertiary amines $\text{R}_1\text{R}_2\text{R}_3\text{NH}^+$	2 700–2 250	Group of relatively sharp bands; broad bands in solid state
Ammonium ion	3 300–3 030 (s) 1 430–1 390 (s)	Group of bands
Imines $=\text{N}=\text{H}$	3 350–3 310 (w) 3 490 (s) 3 490 (s)	Aliphatic Aryl Pyrroles, indoles; band sharp
Imine salts	2 700–2 330 (m–s) 2 200–1 800 (m)	Dilute solutions One or more bands; useful to distinguish from protonated tertiary amines
Primary amide $-\text{CONH}_2$	ca 3 500 (m) ca 3 400 (m)	Lowered ca 150 cm^{-1} in the solid state and on H bonding; often several bands $3\,200\text{--}3\,050\text{ cm}^{-1}$
Secondary amide $-\text{CONH}-$	3 460–3 400 (m) 3 100–3 070 (w)	Two bands; lowered on H bonding and in solid state. Only one band with lactams Extra band with bonded and solid-state samples
Miscellaneous R—H		
$-\text{S}-\text{H}$	2 600–2 550 (w)	Weaker than OH and less affected by H bonding
$\text{P}-\text{H}$ $\begin{array}{c} \text{O} \\ \parallel \\ \text{P} \\ \diagdown \\ \text{OH} \end{array}$	2 440–2 350 (m) 2 700–2 560 (m) 100/137 times the	Sharp Associated OH
$\text{R}-\text{D}$	corresponding RH frequency	Useful when assigning RH bands; deuteration leads to a known shift to lower frequency

TABLE 6.12 Absorption Frequencies of Triple Bonds*Abbreviations Used in the Table*

m, moderately strong

var, of variable strength

m-s, moderate to strong

w-m, weak to moderately strong

s, strong

Group	Band, cm^{-1}	Remarks
Alkynes		
Terminal	3 300 (s) 2 140–2 100 (w-m)* 1 375–1 225 (w-m) 695–575 (m-s)	CH stretching $\text{C}\equiv\text{C}$ stretching Two bands if molecule has axial symmetry
Nonterminal	ca 630 (s) 2 260–2 150 (var)*	Alkyl monosubstituted Symmetrical or nearly symmetrical substitution makes the $\text{C}\equiv\text{C}$ stretching frequency inactive. When more than one $\text{C}\equiv\text{C}$ linkage is present, and sometimes when there is only one, there are frequently more absorption bands in this region than there are triple bonds to account for them.
$\text{R}_1-\text{C}\equiv\text{C}-\text{R}_2$	540–465 (m)	The longer the chain, the lower the frequency
Aryl— $\text{C}\equiv\text{C}$ —	ca 550 (m) ca 350 (var)	
— $\text{C}\equiv\text{C}$ —halogen (Cl, Br, I)	185–160 (var)	
Nitriles — $\text{C}\equiv\text{N}$	2 260–2 200 (var)	Stronger and toward the lower end of the range when conjugated; occasionally very weak or absent
Aliphatic	580–555 (m-s) 560–525 (m-s) 390–350 (s)	
Aromatic	580–540 (s) 430–380 (m)	
Isonitriles $\text{R}-\overset{+}{\text{N}}\equiv\bar{\text{C}}$ or $\text{R}-\text{N}=\text{C}:$	2 175–2 150 (s) 2 150–2 115 (s) 1 595	Very sensitive to changes in substituents Not found for nitriles
Cyanamides $\text{>N}-\text{C}\equiv\text{N}\rightleftharpoons\overset{+}{\text{N}}-\text{C}=\bar{\text{N}}$	2 225–2 210 (s)	

* Conjugation with olefinic or acetylenic groups lowers the frequency and raises the intensity. Conjugation with carbonyl groups usually has little effect on the position of absorption.

TABLE 6.12 Absorption Frequencies of Triple Bonds (*continued*)

Group	Band, cm^{-1}	Remarks
Thiocyanates $\text{R}-\text{S}-\text{C}\equiv\text{N}$	2 175–2 140 (s) 404–400 (s) ca 600 (m–s)	Aryl thiocyanates at the upper end of the range, alkyl at the lower end Aliphatic derivatives
Nitrile <i>N</i> -oxides $-\text{C}\equiv\text{N}\rightarrow\text{O}$	2 305–2 285 (s) 1 395–1 365 (s)	Aryl derivatives
Diazonium salts $\text{R}-\text{N}^+\equiv\text{N}$	2 300–2 230 (m–s)	
Selenocyanates $\text{R}-\text{Se}-\text{C}\equiv\text{N}$	ca 2 160 (m–s) 545–520 ca 390 ca 350

Diazoketones $\text{—CO}—\text{CH}=\overset{+}{\text{N}}=\overset{-}{\text{N}}$	2 100–2 080 2 075–2 050	Monosubstituted Disubstituted

Position of Carbonyl Absorption

Because the carbonyl absorption is one of the most prominent and identifiable bands in the IR spectrum, it is often used diagnostically. The general trends of structural variation on the position of $\text{C}=\text{O}$ stretching frequencies are summarized in six principles, as follows. Details of carbonyl absorptions are recorded in Table 6.14 and for other double bonds in Table 6.15, for aromatic bonds in Table 6.16 and other miscellaneous bonds in Table 6.17.

1. The more electronegative the group X in the system $\text{R}—\text{CO}—\text{X}—$, the higher is the frequency.
2. α,β -Unsaturation lowers the frequency by $15\text{--}40\text{ cm}^{-1}$, except in amides, where little shift is observed; if present it is usually to higher frequency.
3. Further conjugation has relatively little effect.

4. Ring strain in cyclic compounds causes a relatively large shift to higher frequency. This phenomenon provides a remarkably reliable test of ring size, distinguishing clearly between four-, five-, and larger-membered-ring ketones, lactones, and lactams. Six-membered-ring and larger ketones, lactones, and lactams show the normal frequency found for the open-chain compounds.
5. Hydrogen bonding to a carbonyl group causes a shift to lower frequency of $40\text{--}60\text{ cm}^{-1}$. Acids, amides, enolized β -keto carbonyl systems, and *o*-hydroxyphenol and *o*-aminophenyl carbonyl compounds show this effect. All carbonyl compounds tend to give slightly lower values for the carbonyl stretching frequency in the solid state compared with the value for dilute solutions.
6. Where more than one of the structural influences on a particular carbonyl group is operating, the net effect is usually close to additive.

An especially convenient aspect of IR spectroscopy is its practice. A small amount of sample can be pressed between two NaCl or KBr (Table 6.19) disks and the spectrum can be determined without further preparation. A spectrum so obtained is recorded as “neat” or “between salts.” If the sample is a solid, it may be mixed in a mortar and pestle with KBr and then pressed into a disk. The salt disk may be placed directly in the IR beam. In neither case is there a concern about solvent peaks. Of course, solvents may be used. Carbon tetrachloride and chloroform are the most commonly used solvents when the compound requires dissolution. Alternately, the sample may be intimately mixed (mulled) with mineral oil (a hydrocarbon oil). The thick slurry may then be smeared on a salt disk and placed in the spectrometer. The brand of mineral oil used historically is Nujol and such slurries are still called “Nujol mulls.” The transmission characteristics of potential solvents for IR spectroscopy may be found in Table 6.20.

Traditional analog spectrometers were calibrated by taking a second spectrum of polystyrene. The sharp 1641 cm^{-1} band was recorded on the same sheet as the original spectrum. Modern Fourier transform instruments do not usually require this step but still require calibration.

TABLE 6.14 Absorption Frequencies of Carbonyl Bands

All bands quoted are strong.

Groups	Band, cm^{-1}	Remarks
Acid anhydrides —CO—O—CO—		
Saturated	1 850–1 800 1 790–1 740	Two bands usually separated by about 60 cm^{-1} . The higher-frequency band is more intense in acyclic anhydrides, and the lower-frequency band is more intense in cyclic anhydrides.
Aryl and α,β -unsaturated	1 830–1 780 1 700–1 710	
Saturated five-ring	1 870–1 820 1 800–1 750	
All classes	1 300–1 050	
		One or two strong bands due to CO stretching

TABLE 6.14 Absorption Frequencies of Carbonyl Bands (*continued*)

Groups	Band, cm^{-1}	Remarks
Acid chlorides — COCl		
Saturated	1 815–1 790	Acid fluorides higher, bromides and iodides lower
Aryl and α,β -unsaturated	1 790–1 750	
Acid peroxide		
CO—O—O—CO—		
Saturated	1 820–1 810 1 800–1 780	
Aryl and α,β -unsaturated	1 805–1 780 1 785–1 755	
Esters and lactones		
—CO—O—		
Saturated	1 750–1 735	
Aryl and α,β -unsaturated	1 730–1 715	
Aryl and vinyl esters		The $\text{C}=\text{C}$ stretching band also shifts to higher frequency.
$\text{C}=\text{C—O—CO—alkyl}$	1 800–1 750	
Esters with electronegative α substituents; <i>e.g.</i> , >CCl—CO—O—	1 770–1 745	
α -Keto esters	1 755–1 740	
Six-ring and larger lactones	Similar values to the corresponding open-chain esters	
Five-ring lactone	1 780–1 760	
α,β -Unsaturated five-ring lactone	1 770–1 740	When $\alpha\text{-CH}$ is present, there are two bands, the relative intensity depending on the solvent.
β,γ -Unsaturated five-ring lactone, vinyl ester type	ca 1 800	
Four-ring lactone	ca 1 820	
β -Keto ester in H bonding enol form	ca 1 650	
All classes	1 300–1 050	Keto from normal; chelate-type H bond causes shift to lower frequency than the normal ester. The $\text{C}=\text{C}$ band is strong and is usually near $1\,630\text{ cm}^{-1}$. Usually two strong bands due to CO stretching
Aldehydes — CHO		
(See also Table 6.39 for C—H .) All values given below are lowered in liquid-film or solid-state spectra by about $10\text{--}20\text{ cm}^{-1}$. Vapor-phase spectra have values raised about 20 cm^{-1} .		

TABLE 6.14 Absorption Frequencies of Carbonyl Bands (*continued*)

Groups	Band, cm^{-1}	Remarks
Aldehydes —CHO (<i>continued</i>)		
Saturated	1 740–1 720	
Aryl	1 715–1 695	<i>o</i> -Hydroxy or amino groups shift this value to 1 655–1 625 cm^{-1} because of intramolecular H bonding.
α,β -Unsaturated	1 705–1 680	
$\alpha,\beta,\gamma,\delta$ -Unsaturated	1 680–1 660	
β -Ketoaldehyde in enol form	1 670–1 645	Lowering caused by chelate-type H bonding
Ketones >C=O		
All values given below are lowered in liquid-film or solid-state spectra by about 10–20 cm^{-1} . Vapor-phase spectra have values raised about 20 cm^{-1} .		
Saturated	1 725–1 705	
Aryl	1 700–1 680	
α,β -Unsaturated	1 685–1 665	
$\alpha,\beta,\alpha',\beta'$ -Unsaturated and diaryl	1 670–1 660	
Cyclopropyl	1 705–1 685	
Six-ring ketones and larger	Similar values to the corresponding open-chain ketones	
Five-ring ketones	1 750–1 740	α,β Unsaturation, $\alpha,\beta,\alpha',\beta'$ unsaturation, etc., have a similar effect on these values as on those of open-chain ketones.
Four-ring ketones	ca 1 780	
α -Halo ketones	1 745–1 725	Affected by conformation; highest values are obtained when both halogens are in the same plane as the C=O.
α,α' -Dihaloketones	1 765–1 745	
1,2-Diketones, <i>syn-trans</i> -open chains	1 730–1 710	Anti-symmetrical stretching frequency of both C=O's. The symmetrical stretching is inactive in the infrared but active in the Raman.
<i>syn-cis</i> -1,2-Diketones, six-ring	1 760 and 1 730	
<i>syn-cis</i> -1,2-Diketones, five ring	1 775 and 1 760	
<i>o</i> -Amino-aryl or <i>o</i> -hydroxy-aryl ketones	1 655–1 635	Low because of intramolecular H bonding. Other substituents and steric hindrance affect the position of the band.

TABLE 6.14 Absorption Frequencies of Carbonyl Bands (*continued*)

Groups	Band, cm^{-1}	Remarks
Ketones $>\text{C}=\text{O}$ (<i>continued</i>)		
Quinones	1 690–1 660	$\text{C}=\text{C}$ band is strong and is usually near $1\,600\text{ cm}^{-1}$.
Extended quinones	1 655–1 635	
Tropone	1 650	Near $1\,600\text{ cm}^{-1}$ when lowered by H bonding as in tropolones
Carboxylic acids $-\text{CO}_2\text{H}$		
All types	3 000–2 500	OH stretching; a characteristic group of small bands due to combination bands
Saturated	1 725–1 700	The monomer is near $1\,760\text{ cm}^{-1}$, but is rarely observed. Occasionally both bands, the free monomer, and the H-bonded dimer can be seen in solution spectra. Ether solvents give one band near $1\,730\text{ cm}^{-1}$.
α,β -Unsaturated	1 715–1 690	
Aryl	1 700–1 680	
α -Halo-	1 740–1 720	
Carboxylate ions $-\text{CO}_2^-$		
Most types	1 610–1 550	Anti-symmetrical and symmetrical stretching, respectively
	1 420–1 300	
Amides $-\text{CO}-\text{N}<$ (See also Table 6.39 for NH stretching and bending.)		
Primary $-\text{CONH}_2$		
In solution	ca 1 690	Amide I; $\text{C}=\text{O}$ stretching
Solid state	ca 1 650	
In solution	ca 1 600	Amide II: mostly NH bending
Solid state	ca 1 640	
		Amide I is generally more intense than amide II. (In the solid state, amides I and II may overlap.)
Secondary $-\text{CONH}-$		
In solution	1 700–1 670	Amide I
Solid state	1 680–1 630	
In solution	1 550–1 510	Amide II; found in open-chain amides only
Solid state	1 570–1 515	
		Amide I is generally more intense than amide II.
Tertiary	1 670–1 630	Since H bonding is absent, solid and solution spectra are much the same.
Lactams		
Six-ring and larger rings	ca 1 670	Shifted to higher frequency when the N atom is in a bridged system
Five-ring	ca 1 700	
Four-ring	ca 1 745	

TABLE 6.14 Absorption Frequencies of Carbonyl Bands (*continued*)

Groups	Band, cm^{-1}	Remarks
$\text{R}-\text{CO}-\text{N}=\text{C}=\text{C}$		Shifted $+15\text{ cm}^{-1}$ by the additional double bond
$\text{C}=\text{C}-\text{CO}-\text{N}$		Shifted by up to $+15\text{ cm}^{-1}$ by the additional double bond. This is an unusual effect by α,β unsaturation. It is said to be due to the inductive effect of the $\text{C}=\text{C}$ on the well-conjugated $\text{CO}-\text{N}$ system, the usual conjugation effect being less important in such a system.
Imides $-\text{CO}-\text{N}-\text{CO}-$		
Cyclic six-ring	ca 1710 and ca 1700	
Cyclic five-ring	ca 1770 and ca 1700	Shift of $+15\text{ cm}^{-1}$ with α,β unsaturation
Ureas $\text{N}-\text{CO}-\text{N}$		
RNHCONHR	ca 1660	
Six-ring	ca 1640	
Five-ring	ca 1720	
Urethanes $\text{R}-\text{O}-\text{CO}-\text{N}$	1740–1690	Also shows amide II band when nonsubstituted on N
Thioesters and Acids $\text{RCO}-\text{S}-\text{R}'$		
RCOSH	ca 1720	α,β -Unsaturated or aryl acid or ester shifted about -25 cm^{-1}
$\text{RCOS}-\text{alkyl}$	ca 1690	
$\text{RCOS}-\text{aryl}$	ca 1710	

TABLE 6.15 Absorption Frequencies of Other Double Bonds*Abbreviations Used in the Table*

m, moderately strong

TABLE 6.20 Infrared Transmission Characteristics of Selected Solvents

TABLE 6.20 Infrared Transmission Characteristics of Selected Solvents (*continued*)

RAMAN SPECTROSCOPY

Infrared and Raman spectroscopy are related by the fact that both permit the detection of bond vibrations. Like IR spectroscopy, the spectral bands are reported in cm^{-1} . An important difference is that the wavelength and intensity of inelastically scattered light is measured in the Raman spectroscopic method. The “Raman effect” causes the scattered radiation to shift according to the energies of molecular vibrations. Although Raman spectroscopy involves a physical principle different from that in IR spectroscopy, the two techniques are complementary.

Infrared spectroscopy relies on a changing dipole during a bond vibration for absorption of energy to occur. In Raman, it is a change in polarizability in the bond that permits absorption. The simple molecule carbon dioxide, $\text{O}=\text{C}=\text{O}$, is an instructive example. Both $\text{C}=\text{O}$ bonds have dipoles but they oppose each other and the net dipole is 0 Debye (0D). The symmetrical stretch in which both $\text{C}=\text{O}$ bonds simultaneously extend and contract does not change the dipole but is detectable by Raman because the polarizability of the system alters.

Raman scattering is not a very efficient process and an energy source of considerable power is required. This is typically an argon (Ar) laser. A variety of chemical bonds and systems can be detected by modern Raman spectrometers and typical data are summarized in Tables 6.21–6.30.

TABLE 6.21 Raman Frequencies of Single Bonds to Hydrogen and Carbon

Abbreviations Used in the Table

m, moderately strong	vw, very weak
m-s, moderate to strong	w, weak
m-vs, moderate to very strong	w-m, weak to moderately strong
s, strong	w-m, weak to moderately strong
vs, very strong	w-vs, weak to very strong

Group	Band, cm^{-1}	Remarks
Saturated C—H and C—C		
—CH ₃	2969–2967 (s) 2884–2883 (s) ca 1205 (s) 1150–1135 1060–1056 975–835 (s) 280–220	In aryl compounds In unbranched alkyls In unbranched alkyls Terminal rocking of methyl group CH ₂ —CH ₃ torsion

	1 413–1 399 (m) 909–885 (m) 711–684 (w)	Plus $=\text{CH}_2$ stretching bands
	1 270–1 251 (m)	Plus $=\text{CH}$ stretching band
	1 314–1 290 (m)	Plus $=\text{CH}$ stretching band
	1 360–1 322 (w) 830–800 (vw)	Plus $=\text{CH}$ stretching band
Hydroxy O—H		
Free —OH Intermolecularly bonded Aromatic —OH	3 650–3 250 (w) 3 400–3 300 (w) ca 3 160 (s)	
—OH	1 460–1 320 (w) 1 276–1 205 (w-m) 1 260 (w-m)	Common to all OH substituents Primary Secondary

TABLE 6.21 Raman Frequencies of Single Bonds to Hydrogen and Carbon (*continued*)

Group	Band, cm^{-1}	Remarks
Hydroxy O—H (<i>continued</i>)		
C—C—OH primary	1 070–1 050 (m-s) 1 030–960 (m-s) 480–430 (w-m)	CCO stretching CCO deformation
C—C—OH Secondary	1 135–1 120 (m-s) 825–815 (vs) 500–490 (w-m)	
Tertiary	1 210–1 200 (m-s) 755–730 (vs) 360–350 (w-m)	
—CO—O—H	1 305–1 270	CO stretching
N—H and C—N bonds		
Amine >N—H Associated Nonbonded Salts	3 400–3 250 (s) 3 550–3 250 (s) 2 986–2 974	Primary amines show two bands. Often obscured by intense CH stretching bands
—NH ₂	1 650–1 590 (w-vs)	Bending
Amides Primary	3 540–3 500 (w) 3 400–3 380 (w) 1 310–1 250 (s)	Both bands lowered ca 150 cm^{-1} in solid state and H bonding Interaction of NH bending and CN stretching; lowered 50 cm^{-1} in nonbonded state
Secondary	1 150–1 095 (m) 3 491–3 404 (m-s) 1 190–1 130 (m) 931–865 (m-s) 430–395 (w-m)	Rocking of NH ₂ Two bands; lowered in frequency on H bonding and in solid state
—CO—N	607–555 (m)	O=CN bending
C—N—C C	1 070–1 045 (m)	Stretching
>C—N< Primary carbon Secondary α carbon	1 090–1 060 (m) 1 140–1 035 (m)	CN stretching Two bands but often obscured. Strong band at 800 cm^{-1}
Tertiary α carbon	1 240–1 020 (m)	Two bands. Strong band also at 745 cm^{-1}

NUCLEAR MAGNETIC RESONANCE SPECTROSCOPY

Nuclear Magnetic Resonance (NMR) Spectroscopy is by far the most widely used analytical technique in the modern organic chemistry lab. Numerous monographs have been written on this subject. It would be impossible to cover all of the significant points here. The reader who is interested in knowing what the proton (^1H) or carbon (^{13}C) spectrum of a particular compound is directed to the Aldrich Library of NMR Spectra or the Sadtler Library.

A number of resources are also available online. These include software for the prediction and analysis of spectral data and databases. Resources include:

Proton NMR basics:

Nuclear Magnetic Resonance

Table 6.31 presents the nuclear properties of the elements. Hydrogen (^1H) is an almost ideal nucleus for NMR spectroscopy. First, its natural abundance is high so most of the nuclei present in the sample will be detected in the NMR experiment. Second, its sensitivity is high meaning that its signal is readily detected. The nuclei that have been most generally used in organic chemistry are ^1H and ^{13}C although the natural abundance of the latter is low. Advances in instruments have made the acquisition of ^{13}C -NMR spectra routine. Several other nuclei have high natural abundance and occur frequently in organic compounds. These include ^7Li , ^{11}B , ^{14}N , ^{19}F , ^{23}Na , and ^{35}Cl , which are shown in bold type in Table 6.31. Modern NMR spectrometers permit the acquisition of NMR spectra from many nuclei depending on the probe. The most favorable nuclei are those that have spin $1/2$, high natural abundance, high sensitivity, and no quadrupole moment. Of course, the importance of the problem under study will ultimately dictate whether the investigator will invest the time and effort to obtain the spectrum when the experiment is difficult.

Table 6.31 Nuclear properties of the elements

In the following table the magnetic moment μ is in multiples of the nuclear magneton μ_N ($eh/4\pi Mc$) with diamagnetic correction, the spin I is in multiples of $h/2\pi$, and the electric quadrupole moment Q is in multiples of 10^{-28} square meters. Nuclei with spin $\frac{1}{2}$ have no quadrupole moment. The sign of μ and Q is uncertain for those nuclides for which no sign is given. Sensitivity is for equal number of nuclei at constant field. NMR frequency at any magnetic field is the entry for column 5 multiplied by the value of the magnetic field in kilogauss. For example, in a magnetic field of 14.0924 kG, protons (^1H) will precess at a frequency of $4.25760 \times 14.0924 \text{ kG} = 60.000 \text{ MHz}$. In a magnetic field of 23.4924 kG, protons will precess at $4.25760 \times 23.4924 \text{ kG} = 100.00 \text{ MHz}$.

Chemical Shifts

In essence, the chemical shift of a nucleus such as proton (¹H) is its resonance frequency. It is usually expressed in parts per million (ppm) relative to a standard. The most common standard is tetramethylsilane [(CH₃)₄Si, TMS] which defines 0 on the delta (δ) scale and 10 on the older, less used τ scale. A small amount of TMS is typically added to the NMR solution to be examined. The presence of an internal standard minimizes experimental variations. This is particularly important because the chemical shift is typically a change of only a few hertz per megahertz, hence the part per million (ppm) scale. The separation of peaks will be greater in hertz at higher field but spectra obtained at different field strengths are comparable on the ppm scale. Common reference standards are listed in Table 6.32.

TABLE 6.32 Proton Chemical Shifts of Reference Compounds Relative to Tetramethylsilane

Compound	Chemical shift δ, ppm*	Solvent(s)
Tetramethylsilane, (CH ₃) ₄ Si	0.0	CDCl ₃ , CCl ₄
3-(Trimethylsilyl)-1-propanesulfonic acid, sodium salt (DSS), (CH ₃) ₃ SiCH ₂ CH ₂ COONa	0.0	D ₂ O
Sodium acetate	1.90	D ₂ O
1,2-Dibromoethane	3.63	CDCl ₃

Compound	Chemical shift δ , ppm*	Solvent(s)
1,1,2,2-Tetrachloroethane, $\text{Cl}_2\text{HCCHCl}_2$	5.95	CDCl_3 , CCl_4
1,4-Benzoquinone	6.78	CDCl_3 , CCl_4
1,4-Dichlorobenzene	7.23	CCl_4
Chloroform, CHCl_3	7.27	CDCl_3 , CCl_4
Benzene	7.37	CDCl_3 , CCl_4
1,3,5-Trinitrobenzene	9.21	$\text{DMSO}-d_6^\dagger$ CDCl_3

*Shift relative to TMS, first entry in table; \dagger Dimethylsulfoxide- d_6

A typical solution prepared for NMR analysis rarely contains more than a few percent of solute. Thus, protons on the solvent could significantly distort the spectrum. When ^1H -NMR are desired, solvents having no protons (CS_2 or CCl_4) or deuterated solvents are used. Table 6.33 gives the common NMR solvents used. Although modern manufacturing methods typically produce NMR solvents having high isotopic purity, incomplete deuteration of a protonic solvent will result in a residual signal.

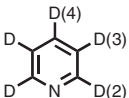

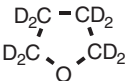

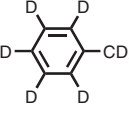

TABLE 6.33 Common NMR Solvents

Solvent	Detail	Group*	δ (ppm)
Acetic acid- d_4	$\text{D}_3\text{C}-\text{COOD}$	CD_2H OH	2.05 11.5 \dagger

TABLE 6.39 Carbon-13 Chemical Shifts (*continued*)

Saturated alicyclic ring systems

**TABLE 6.40** Estimation of Chemical Shifts of Alkane Carbons*Relative to tetramethylsilane*

Positive terms indicate a downfield shift.

$$\delta_C = -2.6 + 9.1n_\alpha + 9.4n_\beta - 2.5n_\gamma + 0.3n_\delta + 0.1n_\epsilon \text{ (plus any correction factors)}$$

where n_α is the number of carbons bonded directly to the i th carbon atom and n_β , n_γ , n_δ , and n_ϵ are the number of carbon atoms two, three, four, and five bonds removed. The constant is the chemical shift for methane.

Chain branching*	Correction factor	Chain branching*	Correction factor
1°(3°)	-1.1	4°(1°)	-1.5
1°(4°)	-3.4	2°(4°)	-7.2
2°(3°)	-2.5	3°(3°)	-9.5
3°(2°)	-3.7	4°(2°)	-8.4

*1° signifies a CH_3- group; 2°, a $-\text{CH}_2-$ group; 3°, a $>\text{CH}-$ group; and 4°, a $>\text{C}<$ group. 1°(3°) signifies a methyl group bound to a $>\text{CH}-$ group, and so on.

Examples: For 3-methylpentane, $\text{CH}_3-\text{CH}_2-\text{CH}(\text{CH}_3)-\text{CH}_2-\text{CH}_3$,

$$\delta_{C=2} = -2.6 + 9.1(2) + 9.4(2) - 2.5 - 1(1)[2^\circ(3^\circ)] = 29.4$$

$$\delta_{C=3} = -2.6 + 9.1(3) + 9.4(2) + (2)[3^\circ(2^\circ)] = 36.2$$

TABLE 6.41 Effect of Substituent Groups on Alkyl Chemical Shifts

These increments are added to the shift value of the appropriate carbon atom as calculated from Table 6.40.

—C≡CH	4.5		5.5		−3.5

*R, alkyl group; Ar, aryl group.

TABLE 6.42 Estimation of Chemical Shift of Carbon Attached to a Double Bond

The olefinic carbon chemical shift is calculated from the equation

$$\delta_C = 123.3 + 10.6n_\alpha + 7.2n_\beta - 7.9n_{\alpha'} - 1.8n_{\beta'} \text{ (plus any steric correction terms)}$$

where n is the number of carbon atoms at the particular position, namely,

Substituents on both sides of the double bond are considered separately. Additional vinyl carbons are treated as if they were alkyl carbons. The method is applicable to alicyclic alkenes; in small rings carbons are counted twice, that is, from both sides of the double bond where applicable. The constant in the equation is the chemical shift for ethylene. The effect of other substituent groups is tabulated below.

Substituent group	β	α	α'	β'
—OR	2	29	−39	−1
—OH	6			−1
—O—CO—CH ₃	−3	18	−27	4
—CO—CH ₃		15	6

ELECTRON SPIN RESONANCE

Electron paramagnetic resonance (EPR) is also referred to as electron spin resonance (ESR). In many respects, it is similar to NMR and the corresponding principles, discussed in the previous section, apply. The critical difference is that an unpaired electron spin is detected in this method instead of a nuclear spin. The method applies only to paramagnetic systems. The electron spin is more readily detected than is a nuclear spin and magnets on EPR instruments are correspondingly smaller and less expensive.

Certain transition metals such as cobalt (Co), copper (Cu), iron (Fe), manganese (Mn), nickel (Ni), and vanadium (V) have unpaired spins and are readily detectable by EPR. Likewise, organic radicals can be detected and studied. Numerous organic radicals have been studied by this method. When an unpaired electron spin is present, it will be observed at a characteristic resonance position. The resonance line is split by nuclei such as protons resulting in spin–spin coupling as observed in NMR. The coupling constant is referred to as “*g*” in EPR rather than “*J*” as in NMR. It is referred to as the hyperfine splitting or hyperfine coupling constant.

Certain radicals are especially stable and are of biological consequence or have been used as antioxidants. TEMPO radicals (TEMPO = 2,2,6,6-tetramethylpiperidin-1-oxyl) have been particularly well studied because they are readily prepared and extremely stable.

A noticeable difference between NMR and EPR is that NMR is typically presented in absorption mode whereas EPR normally is presented in derivative mode. The EPR spectrum may be analyzed mathematically to determine the coupling pattern and thus the structural relationships. A database of software useful in EPR research is available at <http://epr.niehs.nih.gov/software.html>.

Involves protons unless otherwise indicated.

IONIZATION POTENTIALS

The ionization potential is the energy required to remove an electron from an element or compound. Table 6.66A presents the ionization potentials for molecular species. The values are given in electron volts (eV). The values in parentheses are uncertainties in the final figure(s). Smaller numbers indicate lower energies or greater ease of electron removal. Table 6.66B is arranged alphabetically by element. Within an element, the compounds are arranged by increasing molecular weight.

TABLE 6.66A Ionization Potentials of Molecular Species

1 eV = 23.061 kcal·mol^{−1}
Values in parentheses are uncertainties in the final figure(s).

X-RAY DIFFRACTION

The X-ray diffraction method utilizes a monochromatic beam of X-rays to which a solid material is exposed. The beam of radiation interacts with the solid, and is both reflected and diffracted. The reflection pattern is recorded by a detector system sensitive to the X-radiation. Until recently, this involved an intricate mechanical device whose complex

motion permitted X-rays to be recorded over a range of positions, as the detector position changed. Automated instruments using this technology are often referred to as “4-circle diffractometers,” a term that refers to this complex detector motion. Newer X-ray instruments use charge coupled devices (CCDs) to simultaneously detect X-ray diffraction position and intensity over a much broader area. This enhanced detection technology reduces, often dramatically, the time required for data acquisition.

The Bragg equation describes the relationship between the impinging X-radiation, the diffraction angle, and the separation between lattice planes in the crystal under study. The Bragg equation is generally written as

$$\theta = \sin^{-1} (\lambda/2d)$$

where θ is the angle of the diffracted beam (usually called a reflection), λ is the wavelength of the incident X-ray beam, and d is the inter-planar spacing. From the diffraction pattern, both position and intensity, one can obtain structural information about the crystal under study.

Two types of X-ray studies are commonplace: X-ray powder analysis and crystal structure determination. Even in powders, the regular arrangement of atoms within the solid leads to characteristic diffraction patterns. X-ray powder patterns may therefore be used to characterize solids in much the same way that a UV or IR spectrum will give useful information but not necessarily a definitive structure.

The X-ray powder pattern obtained for the sodium salt of 2-propylpentanoic acid ($\text{CH}_3\text{CH}_2\text{CH}_2)_2\text{CHCOO}^-\text{Na}^+$ is shown in Figure 6.2. The X-ray powder pattern was detected over a range 2θ , in this case $2\text{--}40^\circ$ from the incident beam. This is a typical range although other ranges are used as well. The peak intensities are expressed in counts per second (cps) and may vary from experiment to experiment. However, the ratios of the peak heights are characteristic. Thus, X-ray powder patterns obtained from different samples of the same compound should give very similar, if not identical, patterns. Because the X-ray powder patterns are complex, the identity of two spectra suggests that the compounds producing them are also identical.

FIGURE 6.2 X-ray powder pattern of 2-propylpentanoic acid, $(\text{CH}_3\text{CH}_2\text{CH}_2)_2\text{CHCOO}^-\text{Na}^+$.

The determination of a molecular structure from X-ray diffraction data is of critical importance to modern chemical and biological sciences. For small molecules, the structure is normally determined by direct methods. The X-ray diffraction pattern resulting from the interaction of X-rays with the electron clouds of different elements gives a pattern from which the elements present and their connectivity may be deduced. The expected diffraction pattern calculated for an apparent structure is then compared with the observed data to refine the result. Refinement factors (usually expressed as R_w) of 1–3% are common in modern small molecule structure determinations.

The Cambridge Structural Database is a repository for more than 250 000 (as of 2002) small molecule crystal structures. It is accessible at [http:// www.ccdc.cam.ac.uk/](http://www.ccdc.cam.ac.uk/) by subscription.

The process is more complex for such large molecules as proteins. Typically, a model of the amino acid backbone will be constructed first to obtain a general sense of the overall structure. Amino acid sidechains will then be added and the experimental data are again compared with the calculated diffraction pattern. This process is repeated until the complete structure is obtained. Because the uncertainties are larger in these systems, the resolution of the structure is typically reported in Ångstroms. Structures that have a resolution of 3 Å can and do give important information, especially when the gross structure of a protein was previously unknown. Recent improvements in chemical and biological techniques, computers, and X-ray instrumentation (especially in detectors) have made resolutions in the 1–2 Å range more common.

A database, called the Protein Data Bank or “PDB,” is a repository for protein structures. The database may be consulted at no charge and gives access to structures obtained by X-ray methods as well as by NMR and theoretical techniques. The Internet address is <http://www.rcsb.org/pdb>.

LINEAR FREE ENERGY RELATIONSHIPS

Organic chemists have studied the influence of substituents on various reactions for the better part of a century. Linear free energy relationships have played an important role in this pursuit by correlating equilibrium and rate processes. One of the earliest examples is now known as the Hammett equation. It emerged from the observation that the acidities of benzoic acids correlated with the rates at which ethyl esters of benzoic acids hydrolyzed. The relationship was expressed as follows in which K represents an equilibrium constant and k is a rate constant. The proportionality constant, m , is the slope of the log-log data plot for the two processes.

$$m \log \frac{K}{K_0} = \log \frac{k}{k_0}$$

When ΔH and ΔS vary linearly for two processes or when ΔH or ΔS is constant, the free energy relationship will be linear. The common form of the relationship is either

$$\log \frac{K}{K_0} = \sigma \rho \quad \text{or} \quad \log \frac{k}{k_0} = \sigma \rho$$

for equilibrium or rate processes, respectively. The Greek letters rho (ρ) and sigma (σ) symbolize the reaction and substituent constants, respectively. These equations may be used to describe and understand the influence of substituents on a reaction. Separate sigma values are defined by this reaction for *meta* and *para* substituents and provide a measure of the total electronic influence (polar, inductive, and resonance effects) in the absence of conjugation effects. The correlation is not as useful for *ortho*-substituted aromatic compounds because steric or other proximity effects intercede.

Typically in aromatic systems, the inductive effect is transmitted about equally to the *meta* and *para* positions. Consequently, σ_m is an approximate measure of a substituent's inductive effect whereas σ_p gives an approximate measure of a substituent's resonance effect. Consider the dissociation of benzoic acids in water. This process is assigned a reaction constant ρ of 1. The reaction is illustrated using "Sub" to represent a substituent.

We may compare three *para*-substituted benzoic acids. The reference point is *para*-hydrogen, which has a σ_p constant of 0, by definition. The methoxy group is electron donating and has a σ_p constant of -0.27 . Adding electrons to the benzoate anion (structure at right, above) should make the anion less stable. Thus, the ability to dissociate a cation (the acidity) should be diminished. The pK_A is $-\log K_A$ so the higher the pK_A , the lower the acidity (the weaker the acid). In contrast, the nitro group is electron withdrawing. Its σ_p constant is $+0.78$ and its presence in the benzoate anion should be stabilizing. A more stable conjugate base implies a stronger acid and, indeed, the pK_A for 4-nitrobenzoic acid is 3.44. Because these values are logarithmic, there is an order of magnitude difference in the acidities as a result of these substituents.

Comparison of acidities and sigma constants for three benzoic acids

Compound			
Substituent	OCH ₃	H	NO ₂
σ_p	-0.27	0.00	0.78
pK _A	4.49	4.20	3.44

Values of Hammett sigma constants are listed in Table 7.1. Taft sigma* (σ^*) values may be used similarly with respect to aliphatic and alicyclic systems. Values of σ^* constants are also listed in Table 7.1.

The reaction constant ρ is related to the reaction process rather than to the substituents present. A somewhat oversimplified way of considering ρ is to say that it indicates the demand the process makes on the substituents. The acidity of a benzoic acid, C₆H₅COOH, derivative is affected directly by substituents in the aromatic ring. Substituents exert somewhat less influence in phenylacetic acids, C₆H₅CH₂COOH, because the methylene group between carboxylate and the aromatic ring tends to insulate the latter from the former. This “insulation” is even greater for phenylpropanoic acids, C₆H₅CH₂CH₂COOH. The reaction constant ρ for dissociation of benzoic acid in water is set at 1.0. The reaction constants for dissociation of phenylacetic and phenylpropanoic acids are 0.49 and 0.21, respectively, under the same conditions. Values of the reaction parameter for some aromatic and aliphatic systems are given in Tables 7.2 and 7.3.

Since substituent effects in aliphatic systems and in *meta* positions in aromatic systems are essentially inductive in character, σ^* and σ_m values are related by the expression $\sigma_m = 0.217\sigma^* - 0.106$. Substituent effects fall off with increasing distance from the reaction center. The decline is generally a factor of 0.36 for the interposition of a —CH₂— group. This enables σ^* values to be estimated for R—CH₂— groups not otherwise available.

Modified sigma constants have been formulated for situations in which the substituent enters into resonance with the reaction center in an electron-demanding transition state (σ^+) or for an electron-rich transition state (σ^-). Generally, σ^- constants give better correlations in reactions involving phenols, anilines, pyridines, and in nucleophilic substitutions. Values for some modified sigma constants are given in Table 7.4.

EQUILIBRIUM CONSTANTS

The acidities of organic compounds are typically expressed by citing their pK_A values. These are defined as $-\log_{10} K_A$ for the reaction

The equilibrium constant K_A is defined as

$$K_A = \frac{[H^+][A^-]}{[HA]}$$

Thus, for example, the pK_A of water is $-\log_{10} ([H^{\oplus}][HO^{\ominus}]/[H_2O])$ or $(10^{-7}) \cdot (10^{-7})/55.5$. The concentration of protons or hydroxide ions in water is $10^{-7} M$ and the concentration of water in water is $55.5 M$. The equilibrium constant K_A is therefore $10^{-15.74}$. The operator “p” means “ $-\log$ ” so the pK_A of water is 15.7. The equilibrium constant K_w for water is 10^{-14} and is simply the product of $[H^{\oplus}] \cdot [HO^{\ominus}]$.

3-acetamidopyridine

Acidity constants are given for a range of compounds in Table 8.1. When more than one ionizable proton is present, pK_1 , pK_2 , etc. values are given. Cations formed from the indicated compound by protonation are indicated by “(+1)” or “(+2)” for a dication. For example, the dissociation of 3-acetamidopyridine is reported in Table 8.1 as “4.37(+1).” This means dissociation of the compound that is protonated (at the pyridine nitrogen atom).

Temperature values different from $25^{\circ}C$ are given in parentheses as are other relevant variations. For example, the dissociation constant for acetic acid- d_7 is reported in D_2O .

TABLE 8.1 pK_A Values of Organic Materials in Water at 25 °C

Ionic strength μ is zero unless otherwise indicated. The protonation state of cations is designated by a value (+1), (+2), etc. that follows the pK_A value. Neutral species are indicated by (0), if it is not obvious otherwise. The charge state of anionic species is designated by (−1), (−2), etc.

Uric acid

Uridine

Table 8.2 records the acidities of inorganic compounds expressed as their pK_A values (see page 8.2 for a discussion of pK_A). When more than one ionizable proton is present, pK_1 , pK_2 , etc. values are given. Cations formed from the indicated compound by protonation are indicated by “(+1)” or “(+2)” for a dication.

Temperature values different from 25 °C are given in parentheses as are other relevant variations. For example, the dissociation constant for acetic acid- d_1 is reported in D_2O .

TABLE 8.2 Proton-Transfer Reactions of Inorganic Materials in Water at 25 °CThe protonation states of cations are designated by values (+1), (+2), etc. that follow pK_a values.

Substance	Formula	pK_1	pK_2	pK_3	pK_4
Aluminic acid (alumina)	H_3AlO_3	11.2			
Amidophosphoric acid	$H_2NPO(OH)_2$	3.3	8.28		
Aminodisulfonic acid	$HN(SO_3H)_2$			8.50	
Ammonium ion	NH_4^+	9.24			
Arsenic acid	H_3AsO_4	2.25	6.77	11.53	
Arsenous acid	$HAsO_2$ or $HAs(OH)_4$	9.23			
Boric acid, ortho-	H_3BO_3	9.236	12.74		
Boric acid, etra-	$H_2B_4O_7$	4	9		
Carbonic acid	$CO_2 + H_2O$	6.35	10.53		
	(without including dehydration constant)	3.76	10.329		
	$CO_2 + D_2O$ (solvent)	6.77	11.076		
Chloric acid	$HClO_3$	-1.58			
Chlorous acid	$HClO_2$	2.021			
Chlorosulfonic acid	$HOSO_2Cl$	-10.43			
Chromic acid	H_2CrO_4	-0.98	6.50		
Cyanic acid	$HO CN$	3.47			
Deuterium oxide	D_2O (solvent)	14.87			
Diamidophosphoric acid	$(H_2N)_2PO_2H$	4.83			
Dithionic acid	$H_2S_2O_6$	-3.4	-0.2		
Dithionous acid	$H_2S_2O_4$	0.35	2.45		
Ferricyanic acid	$H_3Fe(CN)_6$	< 1			
Ferrocyanic acid	$H_2(Fe(CN)_6)^{2-}$			2.57	4.35
Fluorophosphoric acid	$FPO(OH)_2$		4.79		
Hexapolyphosphoric acid	$H_8P_6O_{19}$	ca 2.1	2.19	5.98	8.13
Hydrazinium(2+) ion (20 °C)	$^+H_3NNH_3^+$	-0.88 (+2)	7.956 (+1)		
Hydrazinosulfuric acid	H_2NNHSO_3H	3.85			
Hydrazoic acid	HN_3	4.64			
Hydrocyanic acid	HCN	9.21			
Hydrogen bromide	HBr	-20.68			
Hydrogen chloride	HCl	-6.1			
Hydrogen fluoride	HF	3.17			
Hydrogen iodide	HI	-9.5			
Hydrogen peroxide	H_2O_2	11.58			
Hydrogen polysulfide (20 °C)	H_2S_4	3.8	6.3		
Hydrogen selenide	H_2Se	3.89	11.0		
Hydrogen sulfide	H_2S	6.96	12.90		
Hydrogen telluride (20 °C)	H_2Te	2.64	11-12		
Hydroperoxy radical	$HO_2 = H^+ + O_2^-$	4.45			
Hydroxide radical	OH^\cdot	11.9			
Hydroxylamine- <i>N,N</i> -di sulfonic acid	$HON(SO_3H)_2$			11.85	
Hydroxylamine- <i>N</i> -sulfonic acid	$HONH-OSO_2H$		ca 12.5		
Hydroxylammonium ion	$HONH_3^+$	5.98			

TABLE 8.2 Proton-Transfer Reactions of Inorganic Materials in Water at 25 °C (*continued*)

Substance	Formula	pK ₁	pK ₂	pK ₃	pK ₄
Hypobromous acid	HBrO	8.597

TABLE 8.4 Indicators for Aqueous Acid–Base Titrations

Table 8.4 lists selected common indicators. The table is arranged according to function over increasing pH range or transition interval given (third column). Note that this range may vary appreciably from one observer to another, and that it is also affected by ionic strength, temperature, and illumination. The values given should therefore be considered to be approximate. These values refer to solutions having low ionic strengths and a temperature of about 25 °C. In the fourth column the pK_A ($-\log K_A$) of the indicator as determined spectrophotometrically is listed. In the fifth and sixth columns, the wavelength of maximum absorption is given for the acidic and basic forms of the indicator, respectively. The lower to higher pH color change is given in the last column. The abbreviations used to describe the colors of the two forms of the indicator are as follows:

- B, Blue
- C, Colorless
- G, Green
- O, Orange
- OBr, Orange-brown
- P, Purple
- R, Red
- V, Violet
- Y, Yellow

Indicator	Chemical name	pH range	pK _A	λ _{max} , nm		Color change
				Acid	Base	
Cresol red (acid range)	<i>o</i> -Cresolsulfonephthalein	0.2–18				R–Y
Cresol purple (acid range)	<i>m</i> -Cresolsulfonephthalein	1.2–2.8	1.51	533		R–Y
Thymol blue (acid range)	Thymolsulfonephthalein	1.2–2.8	1.65	544	430	R–Y
Tropeolin OO	Diphenylamino- <i>p</i> -benzene sodium sulfonate	1.3–3.2	2.0	527		R–Y
2,6-Dinitrophenol	2,6-Dinitrophenol	2.4–4.0	3.69			C–Y
2,4-Dinitrophenol	2,4-Dinitrophenol	2.5–4.3	3.90			C–Y
Methyl yellow	Dimethylaminoazobenzene	2.9–4.0	3.3	508		R–Y
Methyl orange	Dimethylaminoazobenzene sodium sulfonate	3.1–4.4	3.40	522	464	R–O
Bromophenol blue	Tetrabromophenolsulfonephthalein	3.0–4.6	3.85	436	592	Y–BV
Bromocresol green	Tetrabromo- <i>m</i> -cresol-sulfonephthalein	4.0–5.6	4.68	444	617	Y–B
Methyl red	<i>o</i> -Carboxybenzeneazo-dimethylaniline	4.4–6.2	4.95	530	427	R–Y
Chlorophenol red	Dichlorophenolsulfonephthalein	5.4–6.8	6.0		573	Y–R
Bromocresol purple	Dibromo- <i>o</i> -cresolsulfonephthalein	5.2–6.8	6.3	433	591	Y–P
Bromophenol red	Dibromophenolsulfonephthalein	5.2–6.8			574	Y–R
<i>p</i> -Nitrophenol	<i>p</i> -Nitrophenol	5.3–7.6	7.15	320	405	C–Y
Bromothymol blue	Dibromothymolsulfonephthalein	6.2–7.6	7.1	433	617	Y–B
Neutral red	Aminodimethylaminotoluphen-azonium chloride	6.8–8.0	7.4			R–Y
Phenol red	Phenolsulfonephthalein	6.4–8.0	7.9	433	558	Y–R

TABLE 8.4 Indicators for Aqueous Acid–base Titrations (*continued*)

Indicator	Chemical name	pH range	pK _A	λ_{\max} , nm		Color change
				Acid	Base	
<i>m</i> -Nitrophenol	<i>m</i> -Nitrophenol	6.4–8.8	8.3		570	C–Y
Cresol red	<i>o</i> -Cresolsulfonephthalein	7.2–8.8	8.2	434	572	Y–R
<i>m</i> -Cresol purple	<i>m</i> -Cresolsulfonephthalein	7.6–9.2	8.32		580	Y–P
Thymol blue	Thymolsulfonephthalein	8.0–9.6	8.9	430	596	Y–B
Phenolphthalein	Phenolphthalein	8.0–10.0	9.4		553	C–R
α -Naphtholbenzein	α -Naphtholbenzein	9.0–11.0				Y–B
Thymolphthalein	Thymolphthalein	9.4–10.6	10.0		598	C–B
Alizarin yellow	5-(<i>p</i> -Nitrophenylazo)salicylic acid, Na salt	10.0–12.0	11.16			Y–V
Tropeolin O	<i>p</i> -Sulfobenzeneazoresorcinol	11.0–13.0				Y–OBr
Nitramine	2,4,6-Trinitrophenyl-methylnitroamine	10.8–13.0				C–OBr

TABLE 8.6 Compositions of National Institute of Standards and Technology. Standard pH Buffer Solutions*Air weight of material per liter of buffer solution*

Standard	Weight, g
$\text{KH}_3(\text{C}_2\text{O}_4)_2 \cdot 2\text{H}_2\text{O}$, 0.05 M	12.61
Potassium hydrogen tartrate, about 0.034 M	Saturated at 25 °C
Potassium hydrogen phthalate, 0.05 M	10.12
Phosphate (solution 1)	
KH_2PO_4 , 0.025 M	3.39
Na_2HPO_4 , 0.025 M	3.53
Phosphate (solution 2)	
KH_2PO_4 , 0.008665 M	1.179
Na_2HPO_4 , 0.03032 M	4.30
$\text{Na}_2\text{B}_4\text{O}_7 \cdot 10\text{H}_2\text{O}$, 0.01 M	3.80
Carbonate	
NaHCO_3 , 0.025 M	2.10
Na_2CO_3 , 0.025 M	2.65
$\text{Ca}(\text{OH})_2$, about 0.0203 M	Saturated at 25 °C

Standard Reference pH Buffer Solutions

The buffer value for the National Institute of Standards and technology (U.S.) reference pH buffer solutions is given below:

Buffer solution	KH tartrate	0.05 M KH_2 citrate	0.05 M KH phthalate	0.025 M KH_2PO_4 , 0.025 M Na_2HPO_4	0.0087 M KH_2PO_4 , 0.0302 M Na_2HPO_4	0.01 M $\text{Na}_2\text{B}_4\text{O}_7$	0.025 M NaHCO_3 , 0.025 M Na_2CO_3
Buffer value β	0.027	0.034	0.016	0.029	0.016	0.020	0.029

For the secondary pH reference standards, the buffer value is 0.070 for potassium tetroxalate and 0.09 for calcium hydroxide.

To prepare the standard pH buffer solutions recommended by the National Bureau of Standards (U.S.), the indicated weights of the pure materials in Table 8.6 should be dissolved in water of specific conductivity not greater than 5 micromhos. The tartrate, phthalate, and phosphates can be dried for 2 h at 110 °C before use. Potassium tetroxalate and calcium hydroxide need not be dried. Fresh-looking crystals of borax should be used. Before use, excess solid potassium hydrogen tartrate and calcium hydroxide must be removed. Buffer solutions pH 6 or above should be stored in plastic containers and should be protected from carbon dioxide with soda-lime traps. The solutions should be replaced

within 2 to 3 weeks, or sooner if formation of mold is noticed. A crystal of thymol may be added as a preservative.

Buffer Solutions other than Standards

The range of the buffering effect of a single weak acid group is approximately one pH unit on either side of the pK_A . The ranges of some useful buffer systems are collected in Table 8.7. After all the components have been brought together, the pH of the resulting solution should be determined at the temperature to be employed with reference to standard reference solutions. Buffer components should be compatible with other components in the system under study; this is particularly significant for buffers employed in biological studies. Check tables of formation constants to ascertain whether metal-binding character exists.

When there are two or more acid groups per molecule, or a mixture is composed of several overlapping acids, the useful range is larger. Universal buffer solutions consist of a mixture of acid groups which overlap such that successive pK_A values differ by 2 pH units or less. The Prideaux–Ward mixture comprises phosphate, phenyl acetate, and borate plus HCl and covers the range from 2 to 12 pH units. The McIlvaine buffer is a mixture of citric acid and Na_2HPO_4 that covers the range from pH 2.2 to 8.0. The Britton–Robinson system consists of acetic acid, phosphoric acid, and boric acid plus NaOH and covers the range from pH 4.0 to 11.5. A mixture composed of Na_2CO_3 , NaH_2PO_4 , citric acid, and 2-amino-2-methyl-1,3-propanediol covers the range from pH 2.2 to 11.0.

TABLE 8.7 pH Values of Buffer Solutions for Control Purposes

Materials*	pH range
Glycine and HCl	1.0–3.7
Citrate and HCl	1.3–4.7
<i>p</i> -Toluenesulfonate and <i>p</i> -toluenesulfonic acid	1.1–3.3
Formate and HCl	2.8–4.6
Succinic acid and borax	3.0–5.8
Phenyl acetate and HCl	3.5–5.0
Acetate and acetic acid	3.7–5.6
Succinate and succinic acid	4.8–6.3
2-(<i>N</i> -Morpholino)ethanesulfonic acid and NaOH	5.2–7.1
2,2-Bis(hydroxymethyl)-2,2',2''-nitrilotriethanol and HCl	5.8–7.2
KH_2PO_4 and borax	5.8–9.2
<i>N</i> -Tris(hydroxymethyl)methyl-2-aminoethanesulfonic acid and NaOH	6.8–8.2
KH_2PO_4 and Na_2HPO_4	6.1–7.5
<i>N</i> -2-Hydroxyethylpiperazine- <i>N'</i> -2-ethanesulfonic acid and NaOH	6.9–8.3
Triethanolamine and HCl	6.9–8.5
Diethylbarbiturate (veronal) and HCl	7.0–8.5
Tris(hydroxymethyl)aminomethane and HCl	7.2–9.0
<i>N</i> -Tris(hydroxymethyl)methylglycine and HCl	
<i>N,N</i> -Bis(2-hydroxyethyl)glycine and HCl	
Borax and HCl	7.6–8.9
Glycine and NaOH	8.2–10.1
Ammonia (aqueous) and NH_4Cl	8.3–9.2
Ethanolamine and HCl	8.6–10.4

Borax and NaOH	9.4–11.1
Carbonate and hydrogen carbonate	9.2–11.0
Na ₂ HPO ₄ and NaOH	11.0–12.0

General directions for the preparation of buffer solutions of varying pH but fixed ionic strength are given by Bates.* Preparation of McIlvaine buffered solutions at ionic strengths of 0.5 and 1.0 and Britton–Robinson solutions of constant ionic strength have been described by Elving et al.† and Frugoni,‡ respectively.

* Bates, *Determination of pH, Theory and Practice*, Wiley, New York, 1964, pp. 121–122.

ELECTRODE POTENTIALS

TABLE 8.10 Potentials of Selected Half-Reactions at 25 °C

This table is a summary of oxidation–reduction half-reactions arranged in order of decreasing oxidation strength and is useful for selecting reagent systems.

Abbreviations Used in the Table
g, gas liq, liquid s, solid

Half-reaction	<i>E</i> °, V
F ₂ (g) + 2H ⁺ + 2e [−]	= 2HF 3.06
O ₃ + 2H ⁺ + 2e [−]	= O ₂ + H ₂ O 2.07
S ₂ O ₈ ^{2−} + 2e [−]	= 2SO ₄ ^{2−} 2.01
Ag ²⁺ + e [−]	= Ag ⁺ 2.00
H ₂ O ₂ + 2H ⁺ + 2e [−]	= 2H ₂ O 1.77
MnO ₄ [−] + 4H ⁺ + 3e [−]	= MnO ₂ (s) + 2H ₂ O 1.70
Ce(IV) + e [−]	= Ce(III) (in 1 M HClO ₄) 1.61
H ₃ IO ₆ + H ⁺ + 2e [−]	= IO ₃ [−] + 3H ₂ O 1.6
Bi ₂ O ₄ (bismuthate) + 4H ⁺ + 2e [−]	= 2BiO ⁺ + 2H ₂ O 1.59
BrO ₃ [−] + 6H ⁺ + 5e [−]	= $\frac{1}{2}$ Br ₂ + 3H ₂ O 1.52
MnO ₄ [−] + 8H ⁺ + 5e [−]	= Mn ²⁺ + 4H ₂ O 1.51
PbO ₂ + 4H ⁺ + 2e [−]	= Pb ²⁺ + 2H ₂ O 1.455
Cl ₂ + 2e [−]	= 2Cl [−] 1.36
Cr ₂ O ₇ ^{2−} + 14H ⁺ + 6e [−]	= 2Cr ³⁺ + 7H ₂ O 1.33
MnO ₂ (s) + 4H ⁺ + 2e [−]	= Mn ²⁺ + 2H ₂ O 1.23
O ₂ (g) + 4H ⁺ + 4e [−]	= 2H ₂ O 1.229
IO ₃ [−] + 6H ⁺ + 5e [−]	= $\frac{1}{2}$ I ₂ + 3H ₂ O 1.20
Br ₂ (liq) + 2e [−]	= 2Br [−] 1.065
ICl ₂ [−] + e [−]	= $\frac{1}{2}$ I ₂ + 2Cl [−] 1.06
VO ₂ ⁺ + 2H ⁺ + e [−]	= VO ²⁺ + H ₂ O 1.00
HNO ₂ + H ⁺ + e [−]	= NO(g) + H ₂ O 1.00
NO ₃ [−] + 3H ⁺ + 2e [−]	= HNO ₂ + H ₂ O 0.94
2Hg ²⁺ + 2e [−]	= Hg ₂ ²⁺ 0.92
Cu ²⁺ + I [−] + e [−]	= CuI 0.86
Ag ⁺ + e [−]	= Ag 0.799
Hg ₂ ²⁺ + 2e [−]	= 2Hg 0.79
Fe(III) + e [−]	= Fe ²⁺ 0.771
O ₂ (g) + 2H ⁺ + 2e [−]	= H ₂ O ₂ 0.682
2HgCl ₂ + 2e [−]	= Hg ₂ Cl ₂ (s) + 2Cl [−] 0.63
Hg ₂ SO ₄ (s) + 2e [−]	= 2Hg + SO ₄ ^{2−} 0.615
H ₃ AsO ₄ + 2H ⁺ + 2e [−]	= HAsO ₂ + 2H ₂ O 0.581
Sb ₂ O ₅ + 6H ⁺ + 4e [−]	= 2SbO ⁺ + 3H ₂ O 0.559
I ₃ [−] + 2e [−]	= 3I [−] 0.545
Cu ⁺ + e [−]	= Cu 0.52
VO ²⁺ + 2H ⁺ + e [−]	= V ³⁺ + H ₂ O 0.337
Fe(CN) ₆ ^{3−} + e [−]	= Fe(CN) ₆ ^{4−} 0.36
Cu ²⁺ + 2e [−]	= Cu 0.337
UO ₂ ²⁺ + 4H ⁺ + 2e [−]	= U ⁴⁺ + 2H ₂ O 0.334
BiO ⁺ + 2H ⁺ + 3e [−]	= Bi + H ₂ O 0.32
Hg ₂ Cl ₂ (s) + 2e [−]	= 2Hg + 2Cl [−] 0.2676
AgCl(s) + e [−]	= Ag + Cl [−] 0.2223

TABLE 8.11 Half-Wave Potentials (vs. Saturated Calomel Electrode) of Organic Compounds at 25°C (*continued*)

Compound	Solvent system	$E_{1/2}$
Aromatic hydrocarbons (<i>continued</i>)		
1,4,5,8-Tetraphenylnaphthalene	A	-1.39
Toluene	A	-1.98
1,2,3-Trimethylbenzene	A	-1.58
1,2,4-Trimethylbenzene	A	-1.41
1,3,5-Trimethylbenzene	A	-1.50
	B	-1.90
Triphenylene	A	-1.46, -1.55
Triphenylmethane	C	-1.01, -1.68, -1.96
<i>o</i> -Xylene	A	-1.58, -2.04
<i>m</i> -Xylene	A	-1.58
<i>p</i> -Xylene	A	-1.56
Aldehydes		
Acetaldehyde	B, pH 6.8-13	-1.89
Benzaldehyde	McIlvaine buffer, pH 2.2	-0.96, -1.32
Bromoacetaldehyde	pH 8.5	-0.40
	pH 9.8	-1.58, -1.82
Chloroacetaldehyde	Ammonia buffer, pH 8.4	-1.06, -1.66
Cinnamaldehyde	Buffer + EtOH, pH 6.0	-0.9, -1.5, -1.7
Crotonaldehyde	B, pH 1.3-2.0	-0.92
	Ammonia buffer, pH 8.0	-1.30
Dichloroacetaldehyde	Ammonia buffer, pH 8.4	-1.03, -1.67
3,7-Dimethyl-2,6-octadienal	0.1 M Et ₄ NI	-1.56, -2.22
Formaldehyde	0.05 M KOH + 0.1 M KCl, pH 12.7	-1.59
2-Furaldehyde	pH 1-8	-0.86, -0.07 pH
	pH 10	-1.43
Glucose	Phosphate buffer, pH 7	-1.55
Glyceraldehyde	Britton-Robinson buffer, pH 5.0	-1.47
	Britton-Robinson buffer, pH 8.0	-1.55
Glycolaldehyde	0.1 M KOH, pH 13	-1.70
Glyoxal	B, pH 3.4	-1.41
4-Hydroxybenzaldehyde	Britton-Robinson buffer, pH 1.8	-1.16
	Britton-Robinson buffer, pH 6.8	-1.45
4-Hydroxy-2-methoxybenzaldehyde	McIlvaine buffer, pH 2.2	-1.05
	McIlvaine buffer, pH 5.0	-1.16, -1.36
	McIlvaine buffer, pH 8.0	-1.47
<i>o</i> -Methoxybenzaldehyde	Britton-Robinson buffer, pH 1.8	-1.02
	Britton-Robinson buffer, pH 6.8	-1.49
<i>p</i> -Methoxybenzaldehyde	Britton-Robinson buffer, pH 1.8	-1.17
	Britton-Robinson buffer, pH 6.8	-1.48
Methyl glyoxal	A, pH 4.5	-0.83

TABLE 8.11 Half-Wave Potentials (vs. Saturated Calomel Electrode) of Organic Compounds at 25 °C (*continued*)

Compound	Solvent system	$E_{1/2}$
<i>Aldehydes (continued)</i>		
<i>m</i> -Nitrobenzaldehyde	Buffer + 10% EtOH, pH 2.0	-0.28, -1.20
Phthalaldehyde	Buffer, pH 3.1	-0.64, -1.07
	Buffer, pH 7.3	-0.89, -1.29
2-Propenal (acrolein)	pH 4.5	-1.36
	pH 9.0	-1.1
Propionaldehyde	0.1 M LiOH, pH 13	-1.93
Pyrrole-2-carbaldehyde	0.1 M HCl + 50% EtOH	-1.25
Salicylaldehyde	McIlvaine buffer, pH 2.2	-0.99, -1.23
	McIlvaine buffer, pH 5.0	-1.20, -1.30
	McIlvaine buffer, pH 8.0	-1.32
Trichloroacetaldehyde	Ammonia buffer, pH 8.4	-1.35, -1.66
	0.1 M KCl + 50% EtOH	-1.55
<i>Ketones</i>		
Acetone	B, pH 9.3	-1.52
	C	-2.46
Acetophenone	D + McIlvaine buffer, pH 4.9	-1.33
	D + McIlvaine buffer, pH 7.2	-1.58
	D + McIlvaine buffer, pH 1.3	-1.08
7 <i>H</i> -Benz[<i>de</i>]anthracen-7-one	0.1 N H ₂ SO ₄ + 75% MeOH	-0.96
Benzil	D + McIlvaine buffer, pH 1.3	-0.27
	D + McIlvaine buffer, pH 4.9	-0.50
Benzoin	D + McIlvaine buffer, pH 1.3	-0.90
	D + McIlvaine buffer, pH 8.6	-1.49
Benzophenone	D + McIlvaine buffer, pH 1.3	-0.94
	D + McIlvaine buffer, pH 8.6	-1.36
Benzoylacetone	Buffer, pH 2.6	-1.60
	Buffer, pH 5.3 and pH 7.6	-1.68
	Buffer, pH 9.7	-1.72
Bromoacetone	0.1 M LiCl	-0.29
2,3-Butanedione	0.1 M HCl	-0.84
3-Buten-2-one	0.1 M KCl	-1.42
Butyrophenone	0.1 M NH ₄ Cl + 50% EtOH	-1.55
D-Carvone	0.1 M Et ₄ Ni + 80% EtOH	-1.71
Chloroacetone	0.1 M LiCl	-1.18
Coumarin	McIlvaine buffer, pH 2.0	-0.95
	McIlvaine buffer, pH 5.0	-1.11, -1.44
Cyclohexanone	C	-2.45
<i>cis</i> -Dibenzoylethylene	D, pH 1	-0.30
	D, pH 11	-0.62, -1.65
<i>trans</i> -Dibenzoylethylene	D, pH 1	-0.12
	D, pH 11	-0.57, -1.52
Dibenzoylmethane	D, pH 1.3	-0.59
	D, pH 11.3	-1.30, -1.62

TABLE 8.11 Half-Wave Potentials (vs. Saturated Calomel Electrode) of Organic Compounds at 25°C (*continued*)

Compound	Solvent system	$E_{1/2}$
Ketones (<i>continued</i>)		
9,10-Dihydro-9-oxoanthracene	D, pH 2.0	-0.93
1,5-Diphenyl-1,5-pentanedione	A	-2.10
1,5-Diphenylthiocarbazone	D, pH 7.0	-0.6
Flavanone	Acetate buffer + Me ₄ NOH + 50% 2-PrOH, pH 6.1	-1.30
	Acetate buffer + Me ₄ NOH + 50% 2-PrOH, pH 9.6	-1.51
Fluorescein	Acetate buffer, pH 2.0	-0.50
	Phthalate buffer, pH 5.0	-0.65
	Borate buffer, pH 10.1	-1.18, -1.44
Fructose	0.02 M LiCl	-1.76
Girard derivatives of aliphatic ketones	pH 8.2	-1.52
<i>o</i> -Hydroxyacetophenone	D, pH 5	-1.36
<i>p</i> -Hydroxyacetophenone	D, pH 5	-1.46
1,2,3-Indantrione (ninhydrin)	Britton–Robinson buffer, pH 2.5	-0.67, -0.83
	Britton–Robinson buffer, pH 4.5	-0.73, -1.01
	Britton–Robinson buffer, pH 6.8	-0.10, -0.90, -1.20
	Britton–Robinson buffer, pH 9.2	-1.35
α -Ionone	C	-1.59, -2.08
Isatin	Phosphate buffer + citrate buffer, pH 2.9	-0.3, -0.5
	Phosphate buffer + citrate buffer, pH 4.3	-0.3, -0.5, -0.8
	Phosphate buffer + citrate buffer, pH 5.4	-0.8
4-Methyl-3,5-heptadien-2-one	A	-0.64
4-Methyl-2,6-heptanedione	A	-1.28
4-Methyl-3-penten-2-one	D + McIlvaine buffer, pH 1.3	-1.01
	D + McIlvaine buffer, pH 11.3	-1.60
4-Phenyl-3-buten-2-one	D, pH 1.3	-0.72
	D, pH 8.6	-1.27
Phthalide	0.1 M Bu ₄ NI + 50% dioxane	-0.20
Phthalimide	pH 4.2	-1.1, -1.5
	pH 9.7	-1.2, -1.4
Pulegone	C	-1.74
Quinalizarin	Phosphate buffer + 1% EtOH, pH 8.0	-0.56
Testosterone	D + Britton–Robinson buffer, pH 2.6	-1.20
	D + Britton–Robinson buffer, pH 5.8	-1.40
	D + Britton–Robinson buffer, pH 8.8	-1.53, -1.79

TABLE 8.11 Half-Wave Potentials (vs. Saturated Calomel Electrode) of Organic Compounds at 25 °C (*continued*)

Compound	Solvent system	$E_{1/2}$
Quinones		
Anthraquinone	Acetate buffer + 40% dioxane, pH 5.6	-0.51
	Phosphate buffer + 40% dioxane, pH 7.9	-0.71
<i>o</i> -Benzoquinone	Britton–Robinson buffer, pH 7.0	+0.20
	Britton–Robinson buffer, pH 9.0	+0.08
2,3-Dimethylnaphthoquinone	D, pH 5.4	-0.22
1,2-Naphthoquinone	Phosphate buffer, pH 5.0	-0.03
	Phosphate buffer, pH 7.0	-0.13
1,4-Naphthoquinone	Britton–Robinson buffer, pH 7.0	-0.07
	Britton–Robinson buffer, pH 9.0	-0.19
Acids		
Acetic acid	A	-2.3
Acrylic acid	pH 5.6	-0.85
Adenosine-5'-phosphoric acid	HClO ₄ + KClO ₄ , pH 2.2	-1.13
4-Aminobenzenesulfonic acid	0.05 M Me ₄ NI	-1.58
3-Aminobenzoic acid	pH 5.6	-0.67
Anthranilic acid	pH 5.6	-0.67
Ascorbic acid	Britton–Robinson buffer, pH 3.4	+0.17
	Britton–Robinson buffer, pH 7.0	-0.06
Barbituric acid	Borate buffer, pH 9.3	-0.04
Benzoic acid	A	-2.1
Benzoylformic acid	Britton–Robinson buffer, pH 2.2	-0.48
	Britton–Robinson buffer, pH 5.5	-0.85, -1.26
	Britton–Robinson buffer, pH 7.2	-0.98, -1.25
	Britton–Robinson buffer, pH 9.2	-1.25
Bromoacetic acid	pH 1.1	-0.54
2-Bromopropionic acid	pH 2.0	-0.39
Crotonic acid	C	-1.94
Dibromoacetic acid	pH 1.1	-0.03, -0.59
Dichloroacetic acid	pH 8.2	-1.57
5,5-Diethylbarbituric acid	Borate buffer, pH 9.3	0.00
Flavanol	D, pH 5.6	-1.25
	D, pH 7.7	-1.40
Folic acid	Britton–Robinson buffer, pH 4.6	-0.73
Formic acid	0.1 M KCl	-1.66
Fumaric acid	HCl + KCl, pH 2.6	-0.83
	Acetate buffer, pH 4.0	-0.93
	Acetate buffer, pH 5.9	-1.20
2,4-Hexadienedioic acid	Acetate buffer, pH 4.5	-0.97
Iodoacetic acid	pH 1	-0.16
Maleic acid	Britton–Robinson buffer, pH 2.0	-0.70
	Britton–Robinson buffer, pH 4.0	-0.97
	Britton–Robinson buffer, pH 6.0	-1.11, -1.30
	Britton–Robinson buffer, pH 10.0	-1.51

TABLE 8.11 Half-Wave Potentials (vs. Saturated Calomel Electrode) of Organic Compounds at 25°C (*continued*)

Compound	Solvent system	$E_{1/2}$
<i>Acids (continued)</i>		
Mercaptoacetic acid	B, pH 6.8	-0.38
Methacrylic acid	D + 0.1 M LiCl	-1.69
Nitrobenzoic acids	Buffer + 10% EtOH, pH 2.0	-0.2, -0.7
Oxalic acid	B, pH 5.4-6.1	-1.80
2-Oxo-1,5-pentanedioic acid	HCl + KCl, pH 1.8	-0.59
	Ammonia buffer, pH 8.2	-1.30

COOLING MIXTURES

Convenient cooling mixtures can be prepared in several ways. First, an inorganic salt may be mixed with finely shaved dry ice. Such a mixture can be used to maintain temperatures as shown in Table 9.1.

TABLE 9.1 Cooling Mixtures Made from Dry Ice and Salts

Salt	Dry ice, g/100 g	Minimum temperature, °C
CaCl ₂ ·6H ₂ O	41	−9.0
	81	−21.5
	123	−40.3
	143	−55
NH ₄ Cl	25	−15.4
NaBr	66	−28
MgCl ₂	85	−34

A more common method for preparing a low temperature bath is to mix an organic substance with either dry ice or liquid nitrogen. Dry ice (CO₂, −78°C) can be added in small lumps to the solvent until a slight excess of dry ice remains. Alternately, liquid nitrogen (N₂, −196°C) can be poured into the solvent until a slush is formed that consists of the solid–liquid mixture at its melting point.

TABLE 9.2 Dry Ice or Liquid Nitrogen Slush Baths

Substance	Temperature, °C	Substance	Temperature, °C
Ethylene glycol	−13	Acetone–CO ₂	−77
1,2-Dichlorobenzene	−17	Ethyl acetate	−84
Carbon tetrachloride	−22.9	2-Butanone	−87
Bromobenzene	−31	Hexane	−95
Methoxybenzene	−37	Methanol	−98
Chlorobenzene	−45	Carbon disulfide	−112
Bis(2-ethoxyethyl) ether	−44	Bromoethane	−119
<i>N</i> -Methylaniline	−57	Pentane	−130
<i>p</i> -Cymene	−68	2-Methylbutane	−160

HUMIDIFICATION AND DRYING

A saturated aqueous solution in contact with an excess of a definite solid phase at a given temperature will maintain constant humidity in an enclosed space. Table 9.3 identifies a number of salts suitable for this purpose. The aqueous tension (in millimeters of Hg) of a solution at a given temperature is found by multiplying the decimal fraction of the humidity by the aqueous tension at 100% humidity for the specific temperature. For example, the aqueous tension of a saturated solution of NaCl at 20°C is $0.757 \times 17.54 = 13.28$ mmHg and at 80°C is $0.764 \times 355.1 = 271.3$ mmHg.

TABLE 9.3 Humidity (%) Maintained by Saturated Solutions of Various Salts at Specified Temperatures

Solid phase	Temperature, °C						
	10	20	25	30	40	60	80
K ₂ Cr ₂ O ₇			98.0				
K ₂ SO ₄	98	97	97	96	96	96

McReynolds' Constants

The *Kovats retention indices* (R.I.) indicate where compounds will appear on a chromatogram with respect to unbranched alkanes injected with the sample. By definition, the R.I. for pentane is 500, for hexane is 600, for heptane is 700, and so on, regardless of the column used or the operating conditions, although the exact conditions and column must be specified, such as liquid loading, particular support used, and any pretreatment. For example, suppose that on a 20% squalane column at 100°C, the retention times for hexane, benzene, and octane are found to be 15, 16, and 25 min, respectively. On a graph of $\ln t'_R$ (napierian logarithm of the adjusted retention time) of the alkanes versus their retention indices, a R.I. of 653 for benzene is read off the graph. The number 653 for benzene (see the last line of Table 9.8 in the column headed "1" under "Reference compounds") means that it elutes halfway between hexane and heptane on a logarithmic time scale. If the experiment is repeated with a dinonyl phthalate column, the R.I. for benzene is found to be 736 (lying between heptane and octane), which implies that dinonyl phthalate will retard benzene slightly more than squalane will; that is, dinonyl phthalate is slightly more polar than squalane by $\Delta I = 83$ units (the entry in Table 9.8 for dinonyl phthalate in the column headed "1" under "Reference compounds"). The difference gives a measure of solute-solvent interaction due to all intermolecular forces other than London dispersion forces. The latter are the principal solute-solvent effects with squalane.

Now the overall effects due to hydrogen bonding, dipole moment, acid-base properties, and molecular configuration can be expressed as

$$\Sigma \Delta I = ax' + by' + cz' + du' + es'$$

where $x' = \Delta I$ for benzene (the column headed "1" in Table 9.8, intermolecular forces typical of aromatics and olefins), $y' = \Delta I$ for 1-butanol (the column headed "2" in Table 9.8, electron attraction typical of alcohols, nitriles, acids, and nitro and alkyl monochlorides, dichlorides and trichlorides), $z' = \Delta I$ for 2-pentanone (the column headed "3" in Table 9.8, electron repulsion typical of ketones, ethers, aldehydes, esters, epoxides, and dimethylamino derivatives), $u' = \Delta I$ for 1-nitropropane (the column headed "4" in Table 9.8, typical of nitro and nitrile derivatives), and $s' = \Delta I$ for pyridine (or dioxane) (the column headed "5" in Table 9.8).

TABLE 9.8 McReynolds' Constants for Stationary Phases in Gas Chromatography

The McReynolds' constants listed are differences in retention index units between the reference compound run on squalane and on the other phases listed. The last entry in the table shows the absolute retention indices for the reference compounds on squalane. Reference compounds are (1) benzene, (2) 1-butanol, (3) 2-pentanone, (4) 1 nitropropane, and (5) pyridine. (Note that Rohrschneider's constants are based on these reference compounds and may differ slightly from the McReynolds' constants. The reference compounds for Rohrschneider's constants are (1) benzene, (2) ethanol, (3) 2-butanone, (4) nitromethane, and (5) pyridine.) The minimum temperature is that at which normal gas-liquid chromatography (GLC) behavior is expected. Below that temperature, the phase will be a solid or an extremely viscous gum. The maximum temperature is that above which the bleed rate will be excessive.

POLYMERS

General

Polymers are macromolecules that result from combinations of individual building blocks called monomer molecules. Most polymers are regular structures in which a single unit repeats many times. This produces a range of macromolecules that have similar structures and molecular weights. The ensemble of molecules typically exhibit average molecular weights but have characteristic properties. Polymerization of ethylene, $\text{CH}_2=\text{CH}_2$, results in polyethylene, $(-\text{CH}_2-\text{CH}_2-)_n$ such that “ n ” is a range of values. If the average chain possesses 1000 monomer units, chains having values of n such as 998, 999, 1001, 1002, etc. will be present as well. There will be more such chains near the average value and fewer or none when n is far from the average value.

In some polymers, long segments of linear polymer chains are oriented in a regular manner with respect to one another. Such polymers have many of the physical characteristics of crystals and are said to be *crystalline*. Polymers that have polar functional groups show a greater tendency to be crystalline. Orientation is aided by alignment of dipoles on different chains. Van der Waals’ interactions between long hydrocarbon chains may provide sufficient total attractive energy to account for a high degree of regularity within the polymers.

Irregularities such as branch points, co-monomer units, and cross-links lead to *amorphous* polymers. These have less regular structures and typically do not have true melting points. Instead, they have glass transition temperatures at which the rigid and glass-like material becomes a viscous liquid as the temperature is raised.

Elastomers. Elastomer is a generic name for polymers that exhibit rubber-like elasticity. Elastomers are soft yet sufficiently elastic that they can usually be stretched several hundred percent under tension. When the stretching force is removed, they quickly retract and recover their original dimensions.

Polymers that soften or melt and then solidify and regain their original properties on cooling are called *thermoplastic*. A thermoplastic polymer is usually a single strand of linear polymer with few if any cross-links.

Thermosetting Polymers. Polymers that soften or melt on warming and then become infusible solids are called *thermosetting*. The term implies that thermal decomposition has not taken place. Thermosetting plastics contain a cross-linked polymer network that extends through the final material, making it stable to heat and insoluble in organic solvents. Many molded plastics are shaped while molten and are then heated further to become rigid solids of desired shapes.

Synthetic Rubbers. Synthetic rubbers are polymers with rubber-like characteristics that are prepared from dienes or olefins. Rubbers with special properties can also be prepared from other polymers, such as polyacrylates, fluorinated hydrocarbons, and polyurethanes.

Structural Differences. Polymers exhibit structural differences resulting from the type of monomer used, the polymerization method employed, and other factors. A *linear* polymer consists of long segments of single strands that are oriented in a regular manner with respect to one another. *Branched* polymers have substituents attached to the repeating units that extend the polymer laterally. When these units participate in chain propagation and link together chains, a *cross-linked* polymer is formed. A *ladder* polymer results when repeating units have a tetravalent structure such that a polymer consists of two backbone chains regularly cross-linked at short intervals.

Generally polymers involve bonding of the most substituted carbon of one monomeric unit to the least substituted carbon atom of the adjacent unit in a *head-to-tail* arrangement. An example is the formation of polypropylene from propylene. This is shown for three monomer units. The wavy lines indicate that more monomers would lead to extended chains.

Substituents appear on alternate carbon atoms. *Tacticity* refers to the configuration of substituents relative to the backbone axis. In an *isotactic* arrangement, substituents are on the same plane of the backbone axis; that is, the configuration at each chiral center is identical.

In a *syndiotactic* arrangement, the substituents are in an ordered alternating sequence, appearing alternately on one side and then on the other side of the chain, as shown for a segment of a vinyl chloride polymer. If the sidechains are not in any particular order with respect to each other (random), the polymer is said to be *atactic*.

Copolymerization. Copolymerization occurs when a mixture of two or more monomer types polymerizes so that each kind of monomer enters the polymer chain. The fundamental structure resulting from copolymerization depends on the nature of the monomers and the relative rates of monomer reactions with the growing polymer chain. A tendency toward alternation of monomer units is common. Random copolymerization is known but it is rather unusual.

In *graft copolymers* the chain backbone is composed of one kind of monomer and the branches are made up of another kind of monomer. The structure of a *block copolymer* consists of a homopolymer attached to chains of another homopolymer. In either case, *cis* or *trans* (*Z* or *E*) double bond configurations around any double bond not involved in the polymerization will normally be unaltered.

Schematic of a graft copolymer

Schematic of a block copolymer

Dendrimers

A relatively recent development in polymer chemistry is the family of compounds known as dendrimers. The term derives from the Greek *dendra* meaning tree. Tree-like structures of this general type have also been referred to as arborols. Dendrimers differ from typical polymers in that they radiate from a central unit or core rather than being either linear or planar. Dendrimers are built up using a “generational” structure in discrete synthetic steps. As a result, the product is nearer to being a single compound than is a typical polymer. A typical dendrimer consists of a multifunctional core unit. Each functional group of the core unit is elaborated by a further molecular unit, often referred to as a “dendritic wedge.” The core unit is usually designated “generation 0” and additional units radiating from it or prior units are designated as higher generations, that is, generation 1, generation 2, etc. When the synthesis begins at the core and radiates outward, it is called a divergent synthesis. Alternately, synthesis may begin at the outside and terminate with a core unit.

The more common divergent method is illustrated in the following scheme. 1,3,5-Tricarboxybenzene (trimesic acid) serves as the core or generation 0. It could be functionalized by converting it into the tris(acid chloride). Reaction with the secondary amine of diethanolamine would give the tris(amide) hexahydroxy compound shown here. This structure represents generations 0 and 1. Treatment with an appropriately substituted benzyl chloride could lead to the hexaether that comprises generations 0, 1, and 2. There are now a dozen “Y” groups that could be further functionalized in going to generation 3. A difficulty is that the functional or protecting groups present at each stage must be compatible with the chemistry used to make the connections.

A second issue is that when subsequent generations involve sterically demanding structural units, incomplete substitution may occur. Thus, in the final structure shown, five

benzyl ethers might form, rather than six, owing to steric crowding. This would introduce a defect in the dendrimer structure. Indeed, some molecules might possess all six benzyl ethers whereas others might lack one or even two. It must be possible to manipulate the substituents designated "Y" in the presence of ether and amide groups to further extend the dendrimer.

Novel dendrimers have novel and unique properties that make them promising candidates for use in the development of nanoscale devices and in drug delivery systems.

Additives to Polymers

Antioxidants. Antioxidants markedly retard the rate of autoxidation throughout the useful life of the polymer. Chain-terminating antioxidants have a reactive —NH or —OH functional group and include compounds such as secondary aryl amines or hindered phenols. They function by transfer of hydrogen to free radicals, principally to peroxy radicals. Butylated hydroxytoluene is a widely used example.

Peroxide-decomposing antioxidants destroy hydroperoxides, the sources of free radicals in polymers. Phosphites and thioesters such as tris(nonylphenyl) phosphite, distearyl pentaerythritol diphosphite, and dialkyl thiodipropionates are examples of peroxide-decomposing antioxidants.

Antistatic Agents. External antistatic agents are usually quaternary ammonium salts of fatty acids and ethoxylated glycerol esters of fatty acids that are applied to the plastic surface. Internal antistatic agents are compounded into plastics during processing. Carbon blacks provide a conductive path through the bulk of the plastic. Other types of internal agents must bloom to the surface after compounding in order to be active. These latter materials are ethoxylated fatty amines and ethoxylated glycerol esters of fatty acids, which often must be individually selected to match chemically each plastic type.

Antistatic agents require ambient moisture to function. Consequently their effectiveness is dependent on the relative humidity. They provide a broad range of protection at 50% relative humidity. Much below 20% relative humidity, only materials that provide a conductive path through the bulk of the plastic to ground (such as carbon black) will reduce electrostatic charging.

Chain-Transfer Agents. Chain-transfer agents are used to regulate the molecular weight of polymers. These agents react with the developing polymer and interrupt the growth of a particular chain. The products, however, are free radicals that are capable of adding to monomers and initiating the formation of new chains. The overall effect is to reduce the average molecular weight of the polymer without reducing the rate of polymerization. Branching may occur as a result of chain transfer between a growing but rather short chain with another and longer polymer chain. Branching may also occur if the radical end of a growing chain abstracts a hydrogen atom from a carbon atom four or five carbons removed from the end. Thiols are commonly used as chain-transfer agents.

Coupling Agents. Coupling agents are molecular bridges between the interface of an inorganic surface (or filler) and an organic polymer matrix. Titanium-derived coupling agents interact with the free protons at the inorganic interface to form organic monomolecular layers on the inorganic surface. The titanate-coupling-agent molecule has six functions:

where

Type	<i>m</i>	<i>n</i>
Monoalkoxy	1	3
Coordinate	4	2
Chelate	1	2

Function 1 is the attachment of the hydrolyzable portion of the molecule to the surface of the inorganic (or proton-bearing) species.

Function 2 is the ability of the titanate molecule to transesterify.

Function 3 affects performance as determined by the chemistry of alkylate, carboxyl, sulfonyl, phenolic, phosphate, pyrophosphate, and phosphite groups.

Function 4 provides van der Waals' entanglement via long carbon chains.

Function 5 provides thermoset reactivity via functional groups such as methacrylates and amines.

Function 6 permits the presence of two or three pendent organic groups. This allows all functionality to be controlled to the first-, second-, or third-degree levels.

Silane coupling agents are represented by the formula

where Y represents a hydrolyzable group (typically alkoxy); Z is a functional organic group, such as amino, methacryloxy, epoxy; and R typically is a short aliphatic linkage that serves to attach the functional organic group to silicon in a stable fashion. Bonding to surface hydroxy groups of inorganic compounds is accomplished by the —SiY₃ portion, either by direct bonding of this group or more commonly via its hydrolysis product —Si(OH)₃. Subsequent reaction of the functional organic group with the organic matrix completes the coupling reaction and establishes a covalent chemical bond from the organic phase through the silane coupling agent to the inorganic phase.

Flame Retardants. Flame retardants are thought to function via several mechanisms, dependent upon the class of flame retardant used. Halogenated flame retardants are thought to function principally in the vapor phase either as a diluent and heat sink or as a free-radical trap that stops or slows flame propagation. Phosphorus compounds are thought to function in the solid phase by forming a glaze or coating over the substrate that prevents the heat and mass transfer necessary for sustained combustion. With some additives, as the temperature is increased, the flame retardant acts as a solvent for the polymer, causing it to melt at lower temperatures and flow away from the ignition source.

Mineral hydrates, such as alumina trihydrate and magnesium sulfate heptahydrate, are used in highly filled thermosetting resins.

Foaming Agents (Chemical Blowing Agents). Foaming agents are added to polymers during processing to form minute gas cells throughout the product. Physical foaming agents include liquids and gases. Compressed nitrogen is often used in injection molding. Common liquid foaming agents are short-chain aliphatic hydrocarbons in the C₅ to C₇ range and their chlorinated or fluorinated analogs.

The chemical foaming agent used varies with the temperature employed during processing. At relatively low temperatures (15–200°C), the foaming agent is often 4,4'-oxybis(benzenesulfonylhydrazide) or *p*-toluenesulfonylhydrazide. In the midrange (160–232°C), either sodium hydrogen carbonate or 1,1'-azobisformamide is used. For the

high range (200–285°C), there are *p*-toluenesulfonylsemicarbazide, 5-phenyltetrazole and analogs, and trihydrazinotriazine.

Inhibitors. Inhibitors slow or stop polymerization by reacting with the initiator or the growing polymer chain. The free radical formed from an inhibitor must be sufficiently unreactive that it does not function as a chain-transfer agent and begin another growing chain. Benzoquinone is a typical free-radical chain inhibitor. The resonance-stabilized free radical usually dimerizes or disproportionates to produce inert products and end the chain process.

Lubricants. Materials such as fatty acids are added to reduce the surface tension and improve the handling qualities of plastic films.

Plasticizers. Plasticizers are relatively nonvolatile liquids which are blended with polymers to alter their properties by intrusion between polymer chains. Diisooctyl phthalate is a common plasticizer. A plasticizer must be compatible with the polymer to avoid bleeding out over long periods of time. Products containing plasticizers tend to be more flexible and workable.

Ultraviolet Stabilizers. 2-Hydroxybenzophenones represent the largest and most versatile class of ultraviolet stabilizers that are used to protect materials from the degradative effects of ultraviolet radiation. They function by absorbing ultraviolet radiation and by quenching electronically excited states.

Hindered amines, such as 4-(2,2,6,6-tetramethylpiperidinyl) decanedioate, serve as radical scavengers and will protect thin films under conditions in which ultraviolet absorbers are ineffective. Metal salts of nickel, such as dibutyldithiocarbamate, are used in polyolefins to quench singlet oxygen or electronically excited states of other species in the polymer. Zinc salts function as peroxide decomposers.

Vulcanization and Curing. Originally, vulcanization implied heating natural rubber with sulfur, but the term is now also employed for curing polymers. When sulfur is employed, sulfide and disulfide cross-links form between polymer chains. This provides sufficient rigidity to prevent *plastic flow*. Plastic flow is a process in which coiled polymers slip past each other under an external deforming force; when the force is released, the polymer chains do not completely return to their original positions.

Organic peroxides are used extensively for the curing of unsaturated polyester resins and the polymerization of monomers having vinyl unsaturation. The —O—O— bond is split into free radicals which can initiate polymerization or cross-linking of various monomers or polymers.

FORMULAS AND KEY PROPERTIES OF PLASTIC MATERIALS

Acetals

Homopolymer. Acetal homopolymers are prepared from formaldehyde and consist of high-molecular-weight linear polymers of formaldehyde. The trimer of formaldehyde is shown to the left and the structure of the polymer is shown at the right, below.

The good mechanical properties of this homopolymer result from the ability of the oxymethylene chains to pack together into a highly ordered crystalline configuration as the polymers change from the molten to the solid state.

Key properties include high melt point, strength and rigidity, good frictional properties, and resistance to fatigue. Higher molecular weight increases toughness but reduces melt flow.

Copolymer. Acetal copolymers are prepared by copolymerization of 1,3,5-trioxane with small amounts of a co-monomer. Carbon-carbon bonds are distributed randomly in the polymer chain. These carbon-carbon bonds help to stabilize the polymer against thermal, oxidative, and acidic attack.

Acrylics

Poly(methyl methacrylate). Acrylic acid is $\text{H}_2\text{C}=\text{CH}-\text{COOH}$ and methacrylic acid is $\text{H}_2\text{C}=\text{C}(\text{CH}_3)\text{COOH}$. These compounds and their methyl esters are both quite reactive and difficult to store and handle. The monomer used to form poly(methyl methacrylate), 2-hydroxy-2-methylpropanenitrile, is prepared by the following reaction:

2-Hydroxy-2-methylpropanenitrile is then reacted with methanol (or other alcohol) to yield methacrylate ester. Free-radical polymerization is initiated by peroxide or azo catalysts and produce poly(methyl methacrylate) resins having the following formula:

Key properties are good resistance to heat, light, and weathering. This polymer is unaffected by most detergents, cleaning agents, and solutions of inorganic acids, alkalies, and aliphatic hydrocarbons. Poly(methyl methacrylate) has light transmittance of 92% with a haze of 1-3% and its clarity is equal to glass.

Poly(methyl acrylate). The structure of methyl acrylate is $\text{H}_2\text{C}=\text{CH}-\text{COOCH}_3$. The monomer used to prepare poly(methyl acrylate) is produced by the oxidation of propylene. The resin is made by free-radical polymerization initiated by peroxide catalysts and has the following formula:

Poly(methyl acrylate) resins vary from soft, elastic, film-forming materials to hard plastics.

Poly(acrylic acid) and Poly(methacrylic acid). Glacial acrylic acid and glacial methacrylic acid can be polymerized to produce water-soluble polymers having the following structures:

These monomers provide a means for introducing carboxyl groups into copolymers. In copolymers these acids can improve adhesion properties, improve freeze-thaw and mechanical stability of polymer dispersions, provide stability in alkalies (including ammonia), increase resistance to attack by oils, and provide reactive centers for cross-linking by divalent metal ions, diamines, or epoxides.

Functional Group Methacrylate Monomers. Hydroxyethyl methacrylate and dimethylaminoethyl methacrylate produce polymers having the following formulas:

The use of hydroxyethyl (also hydroxypropyl) methacrylate as a monomer permits the introduction of reactive hydroxyl groups into the copolymers. This offers the possibility for subsequent cross-linking with an HO-reactive difunctional agent (diisocyanate, diepoxide, or melamineformaldehyde resin). Hydroxyl groups promote adhesion to polar substrates.

Use of dimethylaminoethyl (also *tert*-butylaminoethyl) methacrylate as a monomer permits the introduction of pendent amino groups which can serve as sites for secondary cross-linking, provide a way to make the copolymer acid-soluble, and provide anchoring sites for dyes and pigments.

Poly(acrylonitrile). Acrylonitrile has the formula $\text{H}_2\text{C}=\text{CH}-\text{C}\equiv\text{N}$. Poly(acrylonitrile) polymers have the following formula:

Alkyds

Alkyds are formulated from polyester resins, cross-linking monomers, and fillers of mineral or glass. The unsaturated polyester resins used for thermosetting alkyds are the reaction products of polyfunctional organic alcohols (glycols) and dibasic organic acids. Key properties of alkyds are dimensional stability, colorability, and arc track resistance. Chemical resistance, however, is generally poor.

Alloys

Polymer alloys are physical mixtures of structurally different homopolymers or copolymers. The mixture is held together by secondary intermolecular forces such as dipole interaction, hydrogen bonding, or van der Waals' forces.

Homogeneous alloys have a single glass transition temperature which is determined by the ratio of the components. The physical properties of these alloys are averages based on the composition of the alloy. Heterogeneous alloys can be formed when graft or block copolymers are combined with a compatible polymer. Alloys of incompatible polymers can be formed if an interfacial agent can be found.

Allyls

Diallyl Phthalate (and Diallyl 1,3-Phthalate). Phthalic acid is 1,2-dicarboxybenzene. The 1,3-isomer is generally referred to as isophthalic acid. These allyl polymers are prepared from

These resulting polymers are solid, linear, internally cyclized, thermoplastic structures containing unreacted allylic groups spaced at regular intervals along the polymer chain. Compounds derived from these polymers that are molded with mineral, glass, or synthetic fiber filling exhibit good electrical properties under high humidity and high temperature conditions. They also show stable low-loss factors, high surface and volume resistivity, and high arc and track resistance.

Cellulosics

Cellulose Triacetate. Cellulose triacetate is prepared according to the following reaction:

Because cellulose triacetate has a high softening temperature, it must be processed in solution. A mixture of dichloromethane and methanol is a common solvent.

resin and the curing resin (usually an aliphatic polyamine) are packaged separately and mixed together immediately before use.

Epoxy novolac resins are produced by glycidation of the low-molecular-weight reaction products of phenol (or cresol) with formaldehyde. Highly cross-linked systems are formed that have superior performance at elevated temperatures.

Fluorocarbon

Poly(tetrafluoroethylene). Poly(tetrafluoroethylene) is prepared from tetrafluoroethylene and consists of repeating units in a predominantly linear chain:

Tetrafluoroethylene polymer has the lowest coefficient of friction of any solid. It has remarkable chemical resistance and a very low brittleness temperature (-100°C). Its dielectric constant and loss factor are low and stable across a broad temperature and frequency range. Its impact strength is high.

Fluorinated Ethylene-Propylene Resin. Polymer molecules of fluorinated ethylene-propylene consist of predominantly linear chains with this structure:

Key properties are its flexibility, translucency, and resistance to all known chemicals except molten alkali metals, elemental fluorine and fluorine precursors at elevated temperatures, and concentrated perchloric acid. It withstands temperatures from -270° to 250°C and may be sterilized repeatedly by all known chemical and thermal methods.

Perfluoroalkoxy Resin. Perfluoroalkoxy resin has the following formula:

It resembles polytetrafluoroethylene and fluorinated ethylene propylene in its chemical resistance, electrical properties, and coefficient of friction. Its strength, hardness, and wear resistance are about equal to the former plastic and superior to that of the latter at temperatures above 150°C .

Poly(vinylidene fluoride). Poly(vinylidene fluoride) consists of linear chains in which the predominant repeating unit is

It has good weathering resistance and does not support combustion. It is resistant to most chemicals and solvents and has greater strength, wear resistance, and creep resistance than the preceding three fluorocarbon resins.

Poly(1-chloro-1,2,2-trifluoroethylene). Poly(1-chloro-1,2,2-trifluoroethylene) consists of linear chains in which the predominant repeating unit is

It possesses outstanding barrier properties to gases, especially water vapor. It is surpassed only by the fully fluorinated polymers in chemical resistance. A few solvents dissolve it at temperatures above 100°C, and it is swollen by a number of solvents, especially chlorinated solvents. It is harder and stronger than perfluorinated polymers, and its impact strength is lower.

Ethylene–Chlorotrifluoroethylene Copolymer. Ethylene–chlorotrifluoroethylene copolymer consists of linear chains in which the predominant 1:1 alternating copolymer is

This copolymer has useful properties from cryogenic temperatures to 180°C. Its dielectric constant is low and stable over a broad temperature and frequency range.

Ethylene–Tetrafluoroethylene Copolymer. Ethylene–tetrafluoroethylene copolymer consists of linear chains in which the repeating unit is

Its properties resemble those of ethylene–chlorotrifluoroethylene copolymer.

Poly(vinyl fluoride). Poly(vinyl fluoride) consists of linear chains in which the repeating unit is

It is used only as a film, and it has good resistance to abrasion and resists staining. It also has outstanding weathering resistance and maintains useful properties from –100 to 150°C.

Nitrile Resins

The principal monomer of nitrile resins is acrylonitrile (see “Polyacrylonitrile”), which constitutes about 70% by weight of the polymer and provides the polymer with good gas barrier and chemical resistance properties. The remainder of the polymer is 20–30% methyl acrylate (or styrene), with 0–10% butadiene to serve as an impact-modifying monomer.

Melamine Formaldehyde

The monomer used for preparing melamine formaldehyde is formed as follows:

Hexamethylolmelamine can further condense in the presence of an acid catalyst; ether linkages can also form (see "Urea Formaldehyde"). A wide variety of resins can be obtained by careful selection of pH, reaction temperature, reactant ratio, amino monomer, and extent of condensation. Liquid coating resins are prepared by reacting methanol or butanol with the initial methylolated products. These can be used to produce hard, solvent-resistant coatings by heating with a variety of hydroxy, carboxyl, and amide functional polymers to produce a cross-linked film.

Phenolics

Phenol-formaldehyde resin. Phenol-formaldehyde resin is prepared from phenol by reaction with formaldehyde. Phenol is an enol, the 2-, 4-, and 6-positions of which are activated for reaction with an electrophile. Phenol is sequentially hydroxymethylated approximately as illustrated below. Dehydration of the phenolic hydroxymethyl groups affords a benzyl cation, a new electrophile that can react with another substituted or unsubstituted molecule of phenol. Both linear polymerization and cross-linking are possible, depending on the ratio of the reactants and the polymerization conditions.

One-Stage Resins. The ratio of formaldehyde to phenol is high enough to allow the thermosetting process to take place without the addition of other sources of cross-links.

Two-Stage Resins The ratio of formaldehyde to phenol is low enough to prevent the thermosetting reaction from occurring during manufacture of the resin. At this point the resin is termed *novolac* resin. Subsequently, hexamethylenetetramine is incorporated into the material to act as a source of chemical cross-links during the molding operation (and conversion to the thermoset or cured state).

Polyamides

Nylon 6, 11, and 12. This class of polymers is polymerized by addition reactions of ring compounds that contain both acid and amine groups on the monomer.

Nylon 6 is polymerized from 2-oxohexamethyleneimine (6 carbons); nylon 11 and 12 are made this way from 11- and 12-carbon rings, respectively.

Nylon 6/6, 6/9, and 6/12. As illustrated below, nylon 6/6 is polymerized from 1,6-hexanedioic acid (six carbons) and 1,6-hexanediamine (six carbons).

1,6-Hexanedioic acid

1,6-Hexanediamine

Poly(hexamethylene 1,6- hexanediamide)

Other nylons are made this way from different combinations of monomers to produce types 6/9, 6/10, and 6/12.

Nylon 6 and 6/6 possess the maximum stiffness, strength, and heat resistance of all the types of nylon. Type 6/6 has a higher melt temperature, whereas type 6 has a higher impact resistance and better processibility. At a sacrifice in stiffness and heat resistance, the higher analogs of nylon are useful primarily for improved chemical resistance in certain environments (acids, bases, and zinc chloride solutions) and for lower moisture absorption.

Aromatic nylons, $[-\text{NH}-\text{C}_6\text{H}_4-\text{CO}-]_n$, (also called aramids) have specialty uses because of their improved clarity.

Poly (amide-imide)

Poly(amide-imide) is the condensation polymer of 1,2,4-benzenetricarboxylic anhydride and various aromatic diamines and has the general structure:

It is characterized by high strength and good impact resistance, and retains its physical properties at temperatures up to to 260°C. Its radiation (gamma) resistance is good.

Polycarbonate

Polycarbonate is a polyester in which dihydric (or polyhydric) phenols are joined through carbonate linkages. The general-purpose type of polycarbonate is based on 2,2-bis(4'-hydroxybenzene) propane (bisphenol A) and has the general structure:

Polycarbonates are the toughest of all thermoplastics. They are window-clear, amazingly strong and rigid, autoclavable, and nontoxic. They have a brittleness temperature of -135°C .

Polyester

Poly(butylene terephthalate). Poly(butylene terephthalate) is prepared in a condensation reaction between dimethyl terephthalate and 1,4-butanediol and its repeating unit has the general structure

This thermoplastic shows good tensile strength, toughness, low water absorption, and good frictional properties, plus good chemical resistance and electrical properties.

Poly(ethylene terephthalate). Poly(ethylene terephthalate) is prepared by the reaction of either terephthalic acid or dimethyl terephthalate with ethylene glycol, and its repeating unit has the general structure

The resin has the ability to be oriented by a drawing process and crystallized to yield a high-strength product.

Unsaturated Polyesters. Unsaturated polyesters are produced by reaction between two types of dibasic acids, one of which is unsaturated, and an alcohol to produce an ester. Double bonds in the body of the unsaturated dibasic acid are obtained by using maleic anhydride or fumaric acid.

PCTA Copolyester. Poly(1,4-cyclohexanedimethylene terephthalic acid) (PCTA) copolyester is a polymer of cyclohexanedimethanol and terephthalic acid, with another acid substituted for a portion of the terephthalic acid otherwise required. It has the following formula:

Polyimides. Polyimides have the following formula:

They are used as high-temperature structural adhesives since they become rubbery rather than melt at about 300°C.

Poly(methylpentene)

Poly(methylpentene) is obtained by a Ziegler-type catalytic polymerization of 4-methyl-1-pentene.

Its key properties are its excellent transparency, rigidity, and chemical resistance, plus its resistance to impact and to high temperatures. It withstands repeated autoclaving, even at 150°C.

Polyolefins

Polyethylene. Polymerization of ethylene results in an essentially straight-chain high-molecular-weight hydrocarbon.

Branching occurs to some extent and can be controlled. Minimum branching results in a “high-density” polyethylene because of its closely packed molecular chains. More branching gives a less compact solid known as “low-density” polyethylene.

A key property is its chemical inertness. Strong oxidizing agents eventually cause some oxidation, and some solvents cause softening or swelling, but there is no known solvent for polyethylene at room temperature. The brittleness temperature is -100°C for both types. Polyethylene has good low-temperature toughness, low water absorption, and good flexibility at subzero temperatures.

Polypropylene. The polymerization of propylene results in a polymer with the following structure:

The desired form in homopolymers is the isotactic arrangement (at least 93% is required to give the desired properties). Copolymers have a random arrangement. In block copolymers a secondary reactor is used where active polymer chains can further polymerize to produce segments that use ethylene monomer.

Polypropylene is translucent and autoclavable and has no known solvent at room temperature. It is slightly more susceptible to strong oxidizing agents than polyethylene.

Polybutylene. Polybutylene is composed of linear chains having an isotactic arrangement of ethyl side groups along the chain backbone.

It has a helical conformation in the stable crystalline form.

Polybutylene exhibits high tear, impact, and puncture resistance. It also has low creep, excellent chemical resistance, and abrasion resistance with coilability.

Ionomer. Ionomer is the generic name for polymers based on sodium or zinc salts of ethylene-methacrylic acid copolymers in which interchain ionic bonding, occurring randomly between the long-chain polymer molecules, produces solid-state properties.

The abrasion resistance of ionomers is outstanding, and ionomer films exhibit optical clarity. In composite structures ionomers serve as a heat-seal layer.

Poly(phenylene sulfide)

Poly(phenylene sulfide) has the following formula:

The recurring *para*-substituted benzene rings and sulfur atoms form a symmetrical rigid backbone.

The high degree of crystallization and the thermal stability of the bond between the benzene ring and sulfur are the two properties responsible for the polymer's high melting point, thermal stability, inherent flame retardance, and good chemical resistance. There are no known solvents of poly(phenylene sulfide) that can function below 205°C.

Polyurethane

Foams. Polyurethane foams are prepared by the polymerization of polyols with isocyanates. One of the most commonly used reactive isocyanates toluenediisocyanate, TDI. It is made from toluene by nitration and then reduction followed by treatment with phosgene. The isocyanate residue reacts readily with alcohols to give carbamates (urethanes) or amines to give ureas.

Commonly used isocyanates are toluenediisocyanate, methylenediphenylisocyanate, and polymeric isocyanates. Polyols used are macroglycols based on either polyester or polyether. The former [poly(ethylene phthalate) or poly(ethylene 1,6-hexanedioate)] have hydroxyl groups that are free to react with the isocyanate. Most flexible foam is made from 80/20 toluene diisocyanate (which refers to the ratio of 2,4-toluenediisocyanate to 2,6-toluene diisocyanate). High-resilience foam contains about 80% 80/20 toluenediisocyanate and 20% poly(methylene diphenyl isocyanate), while semiflexible foam is almost always 100% poly(methylene diphenyl isocyanate). Much of the latter reacts by trimerization to form isocyanurate rings.

Flexible foams are used in mattresses, cushions, and safety applications. Rigid and semiflexible foams are used in structural applications and to encapsulate sensitive components to protect them against shock, vibration, and moisture. Foam coatings are tough, hard, flexible, and chemically resistant.

Elastomeric Fiber. Elastomeric fibers are prepared by the polymerization of polymeric polyols with diisocyanates.

The structure of elastomeric fibers is similar to that illustrated for polyurethane foams.

SILICONES

Silicones are formed in the following multistage reaction:

The silanols formed above are unstable and undergo dehydration. On polycondensation, they give polysiloxanes (or silicones) which are characterized by their three-dimensional branched-chain structure. Various organic groups introduced within the polysiloxane chain impart certain characteristics and properties to these resins.

Methyl groups impart water repellency, surface hardness, and noncombustibility.

Phenyl groups impart resistance to temperature variations, flexibility under heat, resistance to abrasion, and compatibility with organic products.

Vinyl groups strengthen the rigidity of the molecular structure by creating easier cross-linkage of molecules.

Methoxy and alkoxy groups facilitate cross-linking at low temperatures.

Oils and gums are nonhighly branched or straight-chain polymers whose viscosity increases with the degree of polycondensation.

Styrenics

Polystyrene. Polystyrene has the following formula:

Polystyrene is rigid with excellent dimensional stability, has good chemical resistance to aqueous solutions, and is an extremely clear material.

Impact polystyrene contains polybutadiene added to reduce brittleness. The polybutadiene is usually dispersed as a discrete phase in a continuous polystyrene matrix. Polystyrene can be grafted onto rubber particles, which assures good adhesion between the phases.

Acrylonitrile–Butadiene–Styrene (ABS) Copolymers. This basic three-monomer system can be tailored to yield resins with a variety of properties. Acrylonitrile contributes heat resistance, high strength, and chemical resistance. Butadiene contributes impact strength, toughness, and retention of low-temperature properties. Styrene contributes gloss, processibility, and rigidity. ABS polymers are composed of discrete polybutadiene particles grafted with the styrene–acrylonitrile copolymer; these are dispersed in the continuous matrix of the copolymer.

Styrene–Acrylonitrile (SAN) Copolymers. SAN resins are random, amorphous copolymers whose properties vary with molecular weight and copolymer composition. An increase in molecular weight or in acrylonitrile content generally enhances the physical properties of the copolymer but at some loss in ease of processing and with a slight increase in polymer color.

SAN resins are rigid, hard, transparent thermoplastics which process easily and have good dimensional stability—a combination of properties unique in transparent polymers.

Sulfones

Below are the formulas for three polysulfones.

The isopropylidene linkage imparts chemical resistance, the ether linkage imparts temperature resistance, and the sulfone linkage imparts impact strength. The brittleness temperature of polysulfones is -100°C . Polysulfones are clear, strong, nontoxic, and virtually unbreakable. They do not hydrolyze during autoclaving and are resistant to acids, bases, aqueous solutions, aliphatic hydrocarbons, and alcohols.

Thermoplastic Elastomers

Polyolefins. In these thermoplastic elastomers the hard component is a crystalline polyolefin, such as polyethylene or polypropylene, and the soft portion is composed of ethylene-propylene rubber. Attractive forces between the rubber and resin phases serve as labile cross-links. Some contain a chemically cross-linked rubber phase that imparts a higher degree of elasticity.

Styrene-Butadiene-Styrene Block Copolymers. Styrene blocks associate into domains that form hard regions. The midblock, which is normally butadiene, ethylene-butene, or isoprene blocks, forms the soft domains. Polystyrene domains serve as cross-links.

Polyurethanes. The hard portion of polyurethane consists of a chain extender and polyisocyanate. The soft component is composed of polyol segments.

Polyesters. The hard portion consists of copolyester, and the soft portion is composed of polyol segments.

Vinyl

Poly(vinyl chloride) (PVC). Polymerization of vinyl chloride results in the formation of a polymer with the following formula:

When blended with phthalate ester plasticizers, PVC becomes soft and pliable.

Its key properties are good resistance to oils and a very low permeability to most gases.

Poly(vinyl acetate). Poly(vinyl acetate) has the following formula:

Poly(vinyl acetate) is used in latex water paints because of its weathering, quick-drying, recoatability, and self-priming properties. It is also used in hot-melt and solution adhesives.

Poly(vinyl alcohol). Poly(vinyl alcohol) has the following formula:

It is used in adhesives, paper coating and sizing, and textile warp size and finishing applications.

Poly(vinyl butyral). Poly(vinyl butyral) is prepared according to the following reaction:

Its key characteristics are its excellent optical and adhesive properties. It is used as the interlayer film for safety glass.

Poly(vinylidene chloride). Poly(vinylidene chloride) is prepared according to the following reaction:

Random copolymer

Urea Formaldehyde

The reaction of urea with formaldehyde yields the following products, which are used as monomers in the preparation of urea formaldehyde resin.

The reaction conditions can be varied so that only one of these monomers is formed. 1-Hydroxymethylurea and 1,3-bis(hydroxymethyl)urea condense in the presence of an acid catalyst to produce urea formaldehyde resins. A wide variety of resins can be obtained by careful selection of the pH, reaction temperature, reactant ratio, amino monomer, and degree of polymerization. If the reaction is carried far enough, an infusible polymer network is produced.

Liquid coating resins are prepared by reacting methanol or butanol with the initial hydroxymethylureas. Ether exchange reactions between the amino resin and the reactive sites on the polymer produce a cross-linked film.

FORMULAS AND ADVANTAGES OF RUBBERS

Gutta Percha

Gutta percha is a natural polymer of isoprene (3-methyl-1,3-butadiene) in which the configuration around each double bond is *trans*. It is hard and horny and has the following formula:

Natural Rubber

Natural rubber is a polymer of isoprene in which the configuration around each double bond is *cis* (or *Z*):

Its principal advantages are high resilience and good abrasion resistance.

Chlorosulfonated Polyethylene

Chlorosulfonated polyethylene is prepared as follows:

Cross-linking, which can occur as a result of side reactions, causes an appreciable gel content in the final product.

The polymer can be vulcanized to give a rubber with very good chemical (solvent) resistance, excellent resistance to aging and weathering, and good color retention in sunlight.

Epichlorohydrin

Epichlorohydrin is a product of covulcanization of epichlorohydrin (epoxy) polymers with rubbers, especially *cis*-polybutadiene.

Its advantages include impermeability to air, excellent adhesion to metal, and good resistance to oils, weathering, and low temperature.

Nitrile Rubber (NBR, GRN, Buna N)

Nitrile rubber can be prepared as follows:

Nitrile rubber is also known as nitrile–butadiene rubber (NBR), government rubber nitrile (GRN), and Buna N.

It possesses resistance to oils up to 120°C and excellent abrasion resistance and adhesion to metal.

Polyacrylate

Polyacrylate has the following formula:

It possesses oil and heat resistance to 175°C and excellent resistance to ozone.

cis-Polybutadiene Rubber (BR)

cis-Polybutadiene is prepared by polymerization of butadiene by mostly 1,4-addition.

The polybutadiene produced is in the *Z* (or *cis*) configuration.

cis-Polybutadiene has good abrasion resistance, is useful at low temperature, and has excellent adhesion to metal.

Polychloroprene (Neoprene)

Polychloroprene is prepared as follows:

It has very good weathering characteristics, is resistant to ozone and to oil, and is heat-resistant to 100°C.

Ethylene–Propylene–Diene Rubber (EPDM)

Ethylene–propylene–diene rubber is polymerized from 60 parts ethylene, 40 parts propylene, and a small amount of nonconjugated diene. The nonconjugated diene permits sulfur vulcanization of the polymer instead of using peroxide.

It is a very lightweight rubber and has very good weathering and electrical properties, excellent adhesion, and excellent ozone resistance.

Polyisobutylene (Butyl Rubber)

Polyisobutylene is prepared as follows:

It possesses excellent ozone resistance, very good weathering and electrical properties, and good heat resistance.

(Z)-Polyisoprene (Synthetic Natural Rubber)

Polymerization of isoprene by 1,4-addition produces polyisoprene that has a *cis* (or *Z*) configuration.

Polysulfide Rubbers

Polysulfide rubbers are prepared as follows:

where R can be

or

Polysulfide rubbers possess excellent resistance to weathering and oils and have very good electrical properties.

Poly(vinyl chloride) (PVC)

Poly(vinyl chloride) as previously discussed under “Formulas and Key Properties of Plastic Materials” has the following structures:

PVC polymer plus special plasticizers are used to produce flexible tubing which has good chemical resistance.

Silicone Rubbers

Silicone rubbers are prepared as follows:

Other groups may replace the methyl groups.

Silicone rubbers have excellent ozone and weathering resistance, good electrical properties, and good adhesion to metal.

Styrene–Butadiene Rubber (GRS, SBR, Buna S)

Styrene–butadiene rubber is prepared from the free-radical copolymerization of one part by weight of styrene and three parts by weight of 1,3-butadiene. The butadiene is incorporated by both 1,4-addition (80%) and 1,2-addition (20%). The configuration around the double bond of the 1,4-adduct is about 80% *trans*. The product is a random copolymer with these general features:

Styrene–butadiene rubber (SBR) is also known as government rubber styrene (GRS) and Buna S.

Urethane

See Table 10.3.

TABLE 10.3 Properties of Natural and Synthetic Rubbers

Rubber	Specific gravity	Durometer hardness (or Shore)	Ultimate elongation % (23 °C)	Tensile strength, lb·in ⁻² (23 °C)	Service temperature, °C

CHEMICAL RESISTANCE

TABLE 10.4 Resistance of Selected Polymers and Rubbers to Various Chemicals at 20°C

The information in this table is intended to be used only as a general guide. The chemical resistance classifications are E = excellent (30 days of exposure causes no damage), G = good (some damage after 30 days), F = fair (exposure may cause crazing, softening, swelling, or loss of strength), N = not recommended (immediate damage may occur).

Styrene–butadiene rubber			E			N	N	E	N	N	N	N	

TABLE 10.5 Common Abbreviations Used in Polymer Chemistry

Acronym	Expansion
ABA	Acrylonitrile–butadiene–acrylate
ABS	Acrylonitrile–butadiene–styrene copolymer
ABS–PC	Acrylonitrile–butadiene–styrene–polycarbonate alloy
ABS–PVC	Acrylonitrile–butadiene–styrene–poly(vinyl chloride) alloy
ACM	Acrylic acid ester rubber
ACS	Acrylonitrile–chlorinated pe–styrene
AES	Acrylonitrile–ethylene–propylene–styrene
AMMA	Acrylonitrile–methyl methacrylate
AN	Acrylonitrile
APET	Amorphous polyethylene terephthalate
APP	Atactic polypropylene
ASA	Acrylic–styrene–acrylonitrile
BR	Butadiene rubber
BS	Butadiene styrene rubber
CA	Cellulose acetate
CAB	Cellulose acetate–butyrate
CAP	Cellulose acetate–propionate
CN	Cellulose nitrate
CP	Cellulose propionate
CPE	Chlorinated polyethylene
CPET	Crystalline polyethylene terephthalate
CPP	Cast polypropylene
CPVC	Chlorinated polyvinyl chloride
CR	Chloroprene rubber
CTA	Cellulose triacetate
DAM	Diallyl maleate
DAP	Diallyl phthalate
DMT	Terephthalic acid, dimethyl ester
ECTFE	Ethylene–chlorotrifluoroethylene copolymer
EEA	Ethylene–ethyl acrylate
EMA	Ethylene–methyl acrylate
EMAA	Ethylene methacrylic acid
EMAC	Ethylene–methyl acrylate copolymer
EMPP	Elastomer modified polypropylene
EnBA	Ethylene normal butyl acrylate
EP	Epoxy resin, also ethylene–propylene
EPM	Ethylene–propylene rubber
ESI	Ethylene–styrene copolymers
EVA(C)	Polyethylene–vinyl acetate
EVOH	Polyethylene–vinyl alcohol copolymers
FEP	Fluorinated ethylene–propylene copolymers
HDI	Hexamethylene diisocyanate
HDPE	High-density polyethylene
HIPS	High-impact polystyrene
HMDI	Diisocyanato dicyclohexylmethane
IPI	Isophorone diisocyanate
LDPE	Low-density polyethylene
LLDPE	Linear low-density polyethylene
MBS	Methacrylate–butadiene–styrene

TABLE 10.5 Common Abbreviations Used in Polymer Chemistry (*continued*)

Acronym	Expansion
MC	Methyl cellulose
MDI	Methylene diphenylene diisocyanate
MEKP	Methyl ethyl ketone peroxide
MF	Melamine formaldehyde
MMA	Methyl methacrylate
MPEG	Polyethylene glycol monomethyl ether
MPF	Melamine–phenol–formaldehyde
NBR	Nitrile butyl rubber
NDI	Naphthalene diisocyanate
NR	Natural rubber
OPET	Oriented polyethylene terephthalate
OPP	Oriented polypropylene
OSA	Olefin–modified styrene–acrylonitrile
PA	Polyamide
PAEK	Poly(aryl ether–ketone)
PAI	Poly(amide–imide)
PAN	Polyacrylonitrile
PB	Polybutylene
PBAN	Poly(butadiene–acrylonitrile)
PBI	Polybenzimidazole
PBN	Polybutylene naphthalate
PBS	Poly(butadiene–styrene)
PBT	Poly(butylene terephthalate)
PC	Polycarbonate
PCD	Polycarbodiimide
PCT	Poly(cyclohexylene–dimethylene terephthalate)
PCTFE	Polychlorotrifluoroethylene
PE	Polyethylene
PEC	Chlorinated polyethylene
PEG	Poly(ethylene glycol)
PEI	Poly(ether–imide)
PEK	Poly(ether–ketone)
PEN	Polyethylene naphthalate
PES	Polyether sulfone
PET	Polyethylene terephthalate
PF	Phenol–formaldehyde copolymer
PFA	Perfluoroalkoxy resin
PI	Polyimide
PIBI	Poly(isobutylene), Butyl rubber
PMDI	Polymeric methylene diphenylene diisocyanate
PMMA	Poly(methyl methacrylate)
PMP	Poly(methylpentene)
PO	Polyolefins
PP	Polypropylene
PPA	Polyphthalamide
PPC	Chlorinated polypropylene
PPO	Poly(phenylene oxide)
PPS	Poly(phenylene sulfide)
PPSU	Poly(phenylene sulfone)

TABLE 10.5 Common Abbreviations Used in Polymer Chemistry (*continued*)

Acronym	Expansion
PS	Polystyrene
PSF	Polysulfone (also PSU)
PSU	Polysulfone (also PSF)
PTFE	Polytetrafluoroethylene
PU	Polyurethane
PUR	Polyurethane
PVA	Poly(vinyl acetate)
PVAL	Poly(vinyl alcohol)
PVB	poly(vinyl butyrate)
PVC	Poly(vinyl chloride)
PVCA	Poly(vinyl chloride–acetate)
PVDA	Poly(vinylidene acetate)
PVDC	Poly(vinylidene chloride)
PVDF	Poly(vinylidene fluoride)
PVF	Poly(vinyl fluoride)
PVOH	Poly(vinyl alcohol)
SAN	Styrene–acrylonitrile copolymer
SB	Styrene–butadiene copolymer
SBC	Styrene block copolymer
SBR	Styrene butadiene rubber
SMA	Styrene–maleic anhydride (also SMC)
SMC	Styrene–maleic anhydride (also SMA)
TA	Terephthalic acid (also TPA)
TDI	Toluene diisocyanate
TEFE	Ethylene–tetrafluoroethylene copolymer
TPA	Terephthalic acid (also TA)
UF	Urea formaldehyde
ULDPE	Ultralow-density polyethylene
UP	Unsaturated polyester resin
UR	Urethane
VLDPE	Very low-density polyethylene
ZNC	Ziegler-Natta catalyst

GAS PERMEABILITY

TABLE 10.6 Gas Permeability Constants ($10^{10}P$) at 25°C for Polymers and Rubbers

The gas permeability constant P is defined as

$$P = \frac{\text{amount of permeant}}{(\text{area}) \times (\text{time}) \times (\text{driving forced across the film})}$$

The gas permeability constant is the amount of gas expressed in cubic centimeters passed in 1 s through a 1-cm² area of film when the pressure across a film thickness of 1 cm is 1 cmHg and the temperature is 25°C. All tabulated values are multiplied by 10^{10} and are in units of seconds⁻¹ (centimeters of Hg)⁻¹. Other temperatures are indicated by exponents and are expressed in degrees Celsius.

Polymer or rubber	Gas						
	He	N ₂	H ₂	O ₂	CO ₂	H ₂ O	Other
Cellulose (cellophane)	0.005 ²⁰	0.003 2	0.006 5	0.002 1	0.004 7	1 900	0.006 ⁴⁵ (H ₂ S); 0.001 7 (SO ₂)

TABLE 10.7 Vapor Permeability Constants ($10^{10}P$) at 35°C for Polymers

All tabulated values are multiplied by 10^{10} and are in units of seconds⁻¹ (centimeters of Hg)⁻¹.

Polymer	Vapor				
	Benzene	Hexane	Carbon tetrachloride	Ethanol	Ethyl acetate
Cellulose	1.4	0.912	0.836	85.8	13.4
Cellulose acetate	512	2.80	3.74	2980	3595
Poly(acrylonitrile)	2.61	1.59	1.47	0	1.34
Polyethylene, low-density	5300	2910	3810	55.9	513
Polystyrene	10600		6820	0	soluble
Poly(vinyl alcohol)	3.58	2.34	1.61	32.7	2.53

FATS, OILS, AND WAXES

TABLE 10.8 Constants of Fats and Oils

Fat or oil	Solidification point, °C	Specific gravity (15°C/15°C)	Refractive index	Acid value	Saponification value	Iodine value
Animal origin						
Butterfat	20–23	0.91 ^{40°C} _{15°C}	1.455	0.5–35	210–230	26–38
Chicken fat	21–27	0.924		1.2	193–205	66–72
Cod-liver oil	–3	0.92–0.93	0.925 ^{25°C}	5.6	171–189	137–166
Deer fat		0.96–0.97		0.8–5.3	195–200	26–36

TABLE 10.8 Constants of Fats and Oils (*continued*)

Fat or oil	Solidification point, °C	Specific gravity (15°C/15°C)	Refractive index	Acid value	Saponification value	Iodine value
<i>Animal origin (continued)</i>						
Dolphin	-3 to +5	0.91-0.93		2-12	203 (body); 290 (jaw)	127 (body); 33 (jaw)
Goat butter		0.91 - 0.94 ^{38°C} _{38°C}			233-236	25-37
Goose fat	22-24	0.92-0.93		0.6	191-193	58-67
Herring oil		0.92-0.94	0.900 ^{60°C}	1.8-44	170-194	102-149
Horse fat	20-45	0.92-0.93		0-2.4	195-200	75-86
Human fat	15	0.903	1.460		193-200	57-73
Lard oil	-2 to +4	0.913-0.915	1.462	0.1-2.5	193-198	63-79
Lard oil, fatty tissue	27-30	0.93-0.94	1.462	0.5-0.8	195-203	47-67
Menhaden oil	-5	0.92-0.93	1.465 ^{60°C}	3-12	189-193	148-185
Neat's-foot oil	-2 to +10	0.91-0.92	1.464 ^{25°C}	0.1-0.6	193-199	58-75
Porpoise, body oil	-16	0.926		1.2	203	127
Rabbit fat	17-23	0.93-0.94		1.4-7.2	199-203	70-100
Sardine oil	20-22	0.92-0.93	1.466 ^{60°C}	4-25	188-196	130-152
Seal	3	0.915-0.926		1.9-40	188-196	130-152
Shark		0.916-0.919			157-164	115-139
Sperm oil	15.5	0.878-0.884		13	120-137	80-84
Tallow, beef	31-38	0.895		0.25	196-200	35-42
Tallow, mutton	32-41	0.937-0.953	1.457 ^{40°C}	2-14	195-196	48-61
Whale oil	-2 to 0	0.917-0.924	1.460 ^{60°C}	1.9	160-202	90-146
<i>Plant origin</i>						
Acorn	-10	0.916			199	100
Almond	-20 to -15	0.914-0.921		0.5-3.5	183-208	93-103

Babassu oil	22–26	0.893 ^{60 °C}	1.443 ^{60 °C}		247	16
Beechnut oil	–17	0.922			191–196	97–111
Castor oil	–18 to –17	0.960–0.967	1.477	0.1–0.8	175–183	84
Chaulmoogra oil, USP	< –25	0.950 ^{25 °C}			196–213	98–110
Chinese vegetable tallow	24–34	0.918–0.922		2.4	179–206	23–41
Cocoa butter	21.5–23	0.964–0.974	1.457 ^{40 °C}	1.1–1.9	193–195	33–42
Coconut oil	14–22	0.926	1.449 ^{40 °C}	2.5–10	153–262	6–10
Corn (maize) oil	–20 to –10	0.921–0.928	1.473 ^{40 °C}	1.4–2.0	187–193	111–128
Cottonseed oil	–13 to +12	0.918 ^{25 °C} 0.918 ^{25 °C}	1.474 ^{40 °C}	0.6–0.9	194–196	103–111
Hazelnut oil	–18 to –17	0.917			191–197	87
Hemp-seed oil	–28 to –15	0.928–0.934		0.45	190–195	145–162
Linseed oil	–27 to –19	0.930–0.938	1.478 ^{25 °C}	1–3.5	188–195	175–202
Mustard oil, black	16	0.918–0.921	1.475 ^{40 °C}	5.7–7.3	173–175	99–110
Neem oil	–3	0.917	1.462 ^{40 °C}		195	71
Niger-seed oil		0.925	1.471 ^{40 °C}		190	129
Oiticica oil		0.974 ^{25 °C}				140–180
Olive oil	–6	0.914–0.918	1.468 ^{40 °C}	0.3–1.0	185–196	79–88
Palm oil	35–42	0.915	1.458 ^{40 °C}	10	200–205	49–59
Palm kernel oil	24	0.918–0.925	1.457 ^{40 °C}	0.3–0.6	220–231	26–32
Peanut oil	3	0.917–0.926	1.469 ^{40 °C}	0.8	186–194	88–98
Perilla oil		0.930–0.937	1.481 ^{25 °C}		188–194	185–206
Pistachio-nut oil	–10 to –5	0.913–0.919			191	83–87
Poppy-seed oil	–18 to –16	0.924–0.926	1.469 ^{40 °C}	2.5	193–195	128–141
Pumpkin-seed oil	–15	0.923–0.925			188–193	121–130
Rapeseed oil	–10	0.913–0.917	1.471 ^{40 °C}	0.36–1.0	168–179	94–105
Safflower oil	–18 to –13	0.925–0.928	1.462 ^{60 °C}	0.6	188–203	122–141
Sesame oil	–6 to –4	0.919 ^{25 °C} 0.919 ^{25 °C}	1.465 ^{40 °C}	9.8	188–193	103–117
Soybean oil	–16 to –10	0.924–0.927	1.473 ^{40 °C}	0.3–1.8	189–194	122–134
Sunflower-seed oil	–17	0.924–0.926	1.469 ^{40 °C}	11.2	188–193	129–136
Tung oil	–2.5	0.94–0.95	1.517 ^{25 °C}	2	190–197	163–171
White-mustard-seed oil	–16 to –8	0.912–0.916		5.4	171–174	94–98
Wheat-germ oil						125

TABLE 10.9 Constants of Waxes

Wax	Melting point, °C	Specific gravity (15°C/15°C)	Refractive index	Acid value	Saponification value	Iodine value
Bamboo leaf	79–80	0.961 ^{25°C}		14–15	43–44	7.8
Bayberry (myrtle)	47–49	0.99	1.436 ^{80°C}	3–4	205–212	4–9.5
Beeswax, ordinary	62–66	0.95–0.97	1.44–1.48 ^{40°C}	17–21	88–100	8–11
Beeswax, East Indian	61–67	0.95–0.97	1.44 ^{40°C}	5–10.5	87–117	4–10.5
Beeswax, white, USP	61–69	0.95–0.98	1.45–1.47 ^{65°C}	17–24	90–96	7–11
Candelilla	73–77	0.98–0.99	1.45–1.46 ^{85°C}	19–24	55–64	14–20
Cape berry	40–45	1.01	1.45 ^{45°C}	2.5–4.0	211–215	0.5–2.5
Caranda	80–85	0.99–1.00		5.0–9.5	64–79	8–9
Carnauba, No. 1 yellow	86–88	0.99–1.00		1.5–2.5	75–86	
Carnauba, No. 3, crude	86–90	0.99–1.01		3.0–8.5	75–89	
Carnauba, No. 3, refined	86–89	0.96–0.97	1.47 ^{40°C}	3.0–5.0	76–85	7–13.5
Castor oil, hydrogenated	83–88	0.98–0.99 ^{20°C}		1.0–5.0	177–181	2.5–8.5
Chinese insect	80–85	0.95–0.97	1.46 ^{40°C}	2–9	78–93	1.0–2.5
Cotton	68–71	0.96		32	71	25
Cranberry	207–218	0.97–0.98		42–59	131–134	44–53
Esparto	75–79	0.985–0.995		22–27	58–73	7–15

Flax	61–70	0.91–0.99		17–48	37–102	22–29
Japan	49–56	0.97–1.00		4–15	210–235	4–15
Jojoba	11–12	0.86–0.90 ^{25°C}	1.465 ^{25°C}	0.2–0.6	92–95	82–88
Microcrystalline, amber	64–91	0.91–0.94	1.42–1.45 ^{80°C}	0	0	0

PHYSICAL CONSTANTS

TABLE 11.1 Fundamental Physical Constants

A. Defined values

Name of unit	Symbol	Definition
SI base units		
Meter (metre) (preferred spelling in U.S. is meter)	m	1 650 763.73 wavelengths in vacuum of the orange-red line of the spectrum of krypton-86
Kilogram	kg	Mass of a cylinder of platinum–iridium alloy kept at Paris
Second	s	Duration of 9 192 631 770 cycles of the radiation associated with a specified transition of the cesium atom
Ampere	A	Magnitude of the current that, when flowing through each of two long parallel wires separated by one meter in free space, results in a force between the two wires 2×10^{-7} newton for each meter of length
Kelvin (degree Kelvin)	K	Defined in the thermodynamic scale by assigning 273.16 K to the triple point of water (freezing point, $273.15\text{ K} = 0^{\circ}\text{C}$)
Candela	cd	Luminous intensity of 1/600 000 of a square meter of a radiating cavity at the temperature of freezing platinum (2042 K)
Mole	mol	Amount of substance which contains as many specified entities (molecules, atoms, ions, electrons, photons, etc.) as there are atoms of carbon-12 in exactly 0.012 kg of that nuclide
Supplementary SI units		
Radian	rad	The plane angle between two radii of a circle which cut off on the circumference an arc equal in length to the radius
Steradian	sr	The solid angle which, having its vertex in the center of a sphere, cuts off an area of the surface of the sphere equal to that of a square with sides of length equal to the radius of the sphere

B. Derived SI units

Quantity and symbol	Name of SI unit	Symbol and definition
Capacitance (electric), C	farad	$F = C \cdot V^{-1}$
Charge (electric), quantity of electricity, Q	coulomb	$C = A \cdot s$
Conductance (electric), $G (= 1/R)$	siemens	$S = \Omega^{-1}$
Energy, work, quantity of heat, H	joule	$J = \text{kg} \cdot \text{m}^2 \cdot \text{s}^{-2}$

TABLE 11.1 Fundamental Physical Constants (*continued*)

Quantity and symbol	Name of SI unit	Symbol and definition
Force	newton	$N = \text{kg} \cdot \text{m} \cdot \text{s}^{-2}$
Frequency	hertz	$\text{Hz} = \text{s}^{-1}$
Illuminance, illumination	lux	$\text{lx} = \text{lm} \cdot \text{m}^{-2}$
Inductance, L	henry	$H = \Omega \cdot \text{s}$
Luminous flux	lumen	$\text{lm} = \text{cd} \cdot \text{sr}$
Magnetic flux	weber	$\text{Wb} = \text{V} \cdot \text{s}$
Magnetic flux density	tesla	$T = \text{Wb} \cdot \text{m}^{-2}$
Potential difference, E	volt	$V = \text{kg} \cdot \text{m}^2 \cdot \text{s}^{-3} \cdot \text{A}^{-1} = \text{J} \cdot \text{A}^{-1} \cdot \text{s}^{-1}$
Power, radiant flux	watt	$W = \text{kg} \cdot \text{m}^2 \cdot \text{s}^{-3} = \text{J} \cdot \text{s}^{-1}$
Pressure, stress	pascal	$\text{Pa} = \text{N} \cdot \text{m}^{-2} = \text{kg} \cdot \text{m}^{-1} \cdot \text{s}^{-2}$
Resistance (electric), R	ohm	$\Omega = \text{V} \cdot \text{A}^{-1} = \text{kg} \cdot \text{m}^2 \cdot \text{s}^{-3} \cdot \text{A}^{-2}$

C. Recommended Consistent Values of Constants

The digits in parentheses following a numerical value represent the standard deviation of that value in terms of the final listed digits.

Constant	Symbol and value
Anomalous electron moment correction	$(\mu_e/\mu_0) - 1 = 1.159615(15) \times 10^{-3}$
Atomic mass unit	$u = (10^{-3} \text{ kg} \cdot \text{mol}^{-1})/N_A = 1.660566(9) \times 10^{-27} \text{ kg}$
Avogadro constant	$N_A = 6.022045(31) \times 10^{23} \text{ mol}^{-1}$
Bohr magneton	$\mu_B = e\hbar/2m_e c = 9.274078(36) \times 10^{-24} \text{ J} \cdot \text{T}^{-1}$
Bohr radius	$a_0 = 4\pi R_\infty = 0.52917706(44) \times 10^{-10} \text{ m}$
Boltzmann constant	$k = R/N_A = 1.380662(44) \times 10^{-23} \text{ J} \cdot \text{K}^{-1}$
Charge-to-mass ratio for electron	$e/m_e = 1.758805(5) \times 10^{11} \text{ C} \cdot \text{kg}^{-1}$
Compton wavelength of electron	$\lambda_c = \alpha^2/2R_\alpha = 2.426309(4) \times 10^{-12} \text{ m}$
Compton wavelength of neutron	$\lambda_{c,n} = h/m_n c = 1.319591(2) \times 10^{-15} \text{ m}$
Compton wavelength of proton	$\lambda_{c,p} = h/m_p c = 1.321410(2) \times 10^{-15} \text{ m}$
Diamagnetic shielding factor, spherical H ₂ O molecule	$1 + \sigma(\text{H}_2\text{O}) = 1.00002564(7)$
Electron g -factor	$g_e/2 = \mu_e/\mu_B = 1.001159657(4)$
Electron magnetic moment	$\mu_e = 9.284832(36) \times 10^{-24} \text{ J} \cdot \text{T}^{-1}$
Electron radius (classical)	$\alpha\lambda_c = \mu_0 e^2/4\pi m_e = r_e = 2.817938(7) \times 10^{-15} \text{ m}$
Electron rest mass	$m_e = 0.910953(5) \times 10^{-30} \text{ kg}$ $= 5.485803(2) \times 10^{-4} u$
Elementary charge	$e = 1.602189(5) \times 10^{-19} \text{ C}$
Faraday constant	$N_A e = F = 9.648456(27) \times 10^4 \text{ C} \cdot \text{mol}^{-1}$
Fine structure constant	$\mu_0 c e^2/2\hbar = \alpha = 0.007297351(6)$ $1/\alpha = 1.370360(1)$
First radiation constant	$2\pi\hbar c^2 = c_1 = 3.74183(2) \times 10^{-16} \text{ W} \cdot \text{m}^2$
Gas constant (molar)	$R = P_0 V_m/T_0 = 8.31441(26) \text{ J} \cdot \text{mol}^{-1} \cdot \text{K}^{-1}$ $= 82.0568(26) \text{ cm}^3 \cdot \text{atm} \cdot \text{mol}^{-1} \cdot \text{K}^{-1}$ $= 1.98719(6) \text{ cal} \cdot \text{mol}^{-1} \cdot \text{K}^{-1}$
Gravitational constant	$G = 6.672(4) \times 10^{-11} \text{ N} \cdot \text{m}^2 \cdot \text{kg}^{-2}$

TABLE 11.1 Fundamental Physical Constants (*continued*)

Constant	Symbol and value
Gyromagnetic ratio of proton (uncorrected for diamagnetism of H ₂ O)	$\gamma_p = 2.675\,199(8) \times 10^8 \text{ s}^{-1} \cdot \text{T}^{-1}$ $\gamma'_p = 675\,130(8) \times 10^8 \text{ s}^{-1} \cdot \text{T}^{-1}$
Josephson frequency–voltage ratio	$2e/h = 4.835\,939(13) \times 10^{14} \text{ Hz} \cdot \text{V}^{-1}$
Magnetic flux quantum	$\Phi_0 = h/2e = 2.067\,851(5) \times 10^{-15} \text{ Wb}$
Molar standard volume, ideal gas	$V_m = RT_0/P_0 = 0.022\,413\,8(7) \text{ m}^3 \cdot \text{mol}^{-1}$
Muon <i>g</i> -factor	$e\hbar/2m_\mu c = g_\mu/2 = 1.001\,166\,16(31)$
Muon magnetic moment	$\mu_\mu = 4.490\,474(18) \times 10^{-26} \text{ J} \cdot \text{T}^{-1}$
Muon rest mass	$m_\mu = 1.883\,566(11) \times 10^{-27} \text{ kg}$
Neutron rest mass	$m_n = 1.674\,954(9) \times 10^{-27} \text{ kg}$
Normal volume, perfect gas	$V_0 = 2.241\,36(30) \times 10^4 \text{ cm}^3 \cdot \text{mol}^{-1}$
Nuclear magneton	$\mu_N = e\hbar/2m_p c = 5.050\,824(20) \times 10^{-27} \text{ J} \cdot \text{T}^{-1}$
Permeability of vacuum	$\mu_0 = 4\pi \times 10^{-7} \text{ H} \cdot \text{m}^{-1}$
Permittivity of vacuum	$\epsilon_0 = (\mu_0 c^2)^{-1} = 8.854\,187\,82(7) \times 10^{-12} \text{ F} \cdot \text{m}^{-1}$
Planck constant	$h = 6.626\,176(36) \times 10^{-34} \text{ J} \cdot \text{s}$ $\hbar = h/2\pi = 1.054\,589(6) \times 10^{-34} \text{ J} \cdot \text{s}$
Proton magnetic moment:	$\mu_p = 1.410\,617(5) \times 10^{-26} \text{ J} \cdot \text{T}^{-1}$
In Bohr magnetons	$\mu_p/\mu_B = 1.521\,032\,209(16) \times 10^{-3}$
In nuclear magnetons	$\mu_p/\mu_N = 2.792\,845\,6(11)$
Proton rest mass	$m_p = 1.672\,649(9) \times 10^{-27} \text{ kg}$
Quantum–charge ratio	$h/e = 4.135\,701(11) \times 10^{-15} \text{ J} \cdot \text{Hz}^{-1} \cdot \text{C}^{-1}$
Quantum of circulation	$h/m_e = 7.273\,89(1) \times 10^{-4} \text{ J} \cdot \text{s} \cdot \text{kg}^{-1}$
Ratio, electron to proton magnetic moments	$\mu_e/\mu_p = 6.582\,106\,88(7) \times 10^2$
Ratio, <i>kx</i> u (Siegbahn) to angstrom	$= 1.000\,020\,5(56)$
Ratio, muon moment to proton moment	$\mu_\mu/\mu_p = 3.183\,340(7)$
Rydberg constant	$R_\infty = 1.097\,373\,18(8) \times 10^7 \text{ m}^{-1}$
Second radiation constant	$c_2 = hc/k = 1.438\,786(45) \times 10^{-2} \text{ m} \cdot \text{K}$
Speed of light in vacuum	$c = 2.997\,924\,58(12) \times 10^8 \text{ m} \cdot \text{s}^{-1}$
Stefan–Boltzmann constant	$\sigma = (\pi^2/60)k^4/\hbar^3 c^2 = 5.670\,3(7) \times 10^{-8} \text{ W} \cdot \text{m}^{-2} \cdot \text{K}^{-4}$
Thomson cross section	$\sigma_e = 8\pi r_e^2/3 = 6.652\,448(33) \times 10^{-28} \text{ m}^2$
Voltage–wavelength product	$V\lambda = 1.239\,852(3) \times 10^{-6} \text{ eV} \cdot \text{m}$
Wien displacement constant	$b = 0.289\,78(4) \text{ cm} \cdot \text{K}$
Zeeman splitting constant	$\mu_B/hc = 4.668\,58(4) \times 10^{-5} \text{ cm}^{-1} \cdot \text{G}^{-1}$
Energy equivalents:	
1 atomic mass unit	$u = 931.501\,6(26) \text{ MeV}$
1 proton mass	$m_p = 938.279\,6(27) \text{ MeV}$
1 neutron mass	$m_n = 939.573\,1(27) \text{ MeV}$
1 muon mass	$m_\mu = 105.659\,48(35) \text{ MeV}$
1 electron mass	$m_e = 0.511\,003\,4(14) \text{ MeV}$
1 electronvolt	$1 \text{ eV}/k = 1.160\,450(36) \times 10^4 \text{ K}$ $1 \text{ eV}/hc = 8.065\,479(21) \times 10^3 \text{ cm}^{-1}$ $1 \text{ eV}/h = 2.417\,970(6) \times 10^{14} \text{ Hz}$

TRANSFORMATIONS

TABLE 11.5 Conversion Formulas for Solutions Having concentrations expressed in Various Ways

Abbreviations Used in the Table		
wt %, weight percent of solute	<i>m</i> , molality	
MW ₁ , molecular weight of solute	<i>M</i> , molarity	
MW ₂ , molecular weight of solvent	<i>n</i> , mole fraction	
<i>d</i> , density of solution (g · mL ⁻¹)	<i>G</i> , grams of solute per liter of solution	

To obtain	From	Compute
molarity	weight per cent of solute	$M = \frac{10 \, d(\text{wt } \%) }{MW_1}$
molarity	molality	$M = \frac{1000 \, dm}{1000 + (MW_1)m}$
molarity	grams of solute per liter of solution	$M = \frac{G}{MW_1}$
molarity	mole fraction	$M = \frac{1000 \, dn}{n(NW_1) + MW_2(1 - n)}$
mole fraction	weight per cent of solute	$n = \frac{(\text{wt } \%)/MW_1}{(\text{wt } \%)/MW_1 + (100 - \text{wt } \%)MW_2}$
mole fraction	molality	$n = \frac{(MW_2)m}{(MW_2)m + 1000}$
mole fraction	molarity	$n = \frac{M(MW_2)}{M(MW_2 - MW_1) + 1000 \, d}$

TABLE 11.5 Conversion Formulas for Solutions Having concentrations expressed in Various Ways (continued)

To obtain	From	Compute
mole fraction	grams of solute per liter of solution	$n = \frac{G(MW_2)}{G(MW_2 - MW_1) + 1000 d(MW_1)}$
weight percent of solute	mole fraction	$\text{wt } \% = \frac{100 n(MW_1)}{n(MW_1) + MW_2(1 - n)}$
weight percent of solute	grams of solute per liter of solution	$\text{wt } \% = \frac{G}{10 d}$
weight percent of solute	molarity	$\text{wt } \% = \frac{M(MW_1)}{10 d}$
weight percent of solute	molality	$\text{wt } \% = \frac{100 m(MW_1)}{1000 + m(MW_1)}$
molality	molarity	$m = \frac{1000 M}{1000 d - M(MW_1)}$
molality	grams of solute per liter of solution	$m = \frac{1000 G}{MW_1(1000 d - G)}$
molality	weight percent of solute	$m = \frac{1000(\text{wt } \%)}{MW_1(100 - \text{wt } \%)}$
molality	mole fraction	$m = \frac{1000 n}{MW_2 - n(MW_2)}$

TABLE 11.6 Conversion Factors

The data have been compared with the *International Standard ISO 31* (1979–80) and the *American Society for Testing and Materials Standard for Metric Practice E 380-79*. Relations which are exact are indicated by an asterisk (*). Factors in parentheses are also exact.
